networks. The first prototype of PeerSoN is designed around a PKI, though some studies are being conducted for weakening this assumption. Each user has a unique ID, possibly computed as a hash of the user’s email. The DHT is used to trace the user’s network presence. An index file, containing a list of new content generated by the user, is also registered in the DHT.

Persona (Baden et al., 2009) is designed as a set of social networking services. It uses an interesting attribute-based encryption protocol for protecting access to users’ content. It allows each user to create various groups of “friends”, by assigning proper attribute credentials. Content can then be associated with a publication policy and made available only to a restricted audience.

Safebook (Cutillo et al., 2009) is based on a DHT and a network of socially close peers, defined Matryoshka. Peers in a user’s Matryoshka are trusted and support the user by anonymizing communications and replicating content and profile information. Safebook exploits a more traditional certification authority. In fact, a user’s public key cannot be calculated from his identity, and all public/private key pairs are generated locally by the peers.

DECENT (Jahid et al., 2012) is a decentralized architecture for social networks that uses a distributed hash table to store user data, and offers cryptographic protections for confidentiality and integrity, as well as support for flexible attribute policies and fast revocation. DECENT ensures that neither data nor social relationships are visible to unauthorized users and provides availability through replication and authentication of updates.

AGENT-BASED SOCIAL NETWORKS

Agents and multi-agent systems are an interesting areas in software research that contributed to the development of the theory and the practice of complex distributed systems (Jennings et al., 1995). In particular, a multi-agent system offers the right abstraction for representing a decentralized and

Figure 1. An example of architecture of agent-based social network

peer-to-peer system (Moro et al., 2002) and may provide an appropriate framework for developing peer-to-peer applications (Koubarakis, 2003). Moreover, multi-agent systems share with social networks both the structure and the scope, since they are composed of individuals connected with some kinds of relationship and they are realized for accomplishing individual and/or common goals (Franchi & Poggi, 2012). Therefore, it is natural to think about synergies between social network and multi-agent system research and application and about the use of multi-agent coordination algorithms for the development of typical social network services. In fact, multi-agent technologies and techniques offer the necessary functions to the users of a social network such as security and trust supports (Yu & Singh, 2000; Franchi et al., 2013) and collaborative and organizational supports (Hattori et al., 1999; Yoshida et al., 2003). In particular, in an agent-based social network a user can take advantage of a set of agents that can help or even replace the user in her/his actions in the social network. For example, Figure 1 shows an example of architecture of agent-based social network; in particular, in such an architecture, each user can take advantage of a set of different personal agents: a personal assistant (PA) agent

helps the user in the interaction with the other users and with the other personal agents; a resource manager (RM) agent supports the management and sharing of resources with other users; the information filtering (IF) and information pushing (IP) agents help the user to find the relevant information and to exchange messages when she/he is offline; finally, the collaborative and organizational agent supports the coordination with the other users.

Several interesting works demonstrate how multi-agent systems are a suitable means for implementing social networks and their services. ReferralWeb (Kautz et al., 1997), Yenta (Foner, 1997), Community Organizer (Hattori et al., 1999), Shine (Yoshida et al., 2003), MARS (Yu & Singh, 2003), Blogracy (Franchi et al., 2013) and MASCRM (Olszak, 2013) are the most interesting.

ReferralWeb is an agent based interactive system for reconstructing, visualizing, and searching social networks on the World-Wide Web, whose main focus is selecting an expert of a given field in one's (extended) social network (Kautz et al., 1997). In ReferralWeb a social network is modeled by a graph, where the nodes represent individuals, and an edge between nodes indicates that a direct relationship between the individuals has been dis-

covered. For ReferralWeb a direct relationship is implied when the names are in close proximity in any documents publicly available on the Web, e.g., home pages, co-authorship in published papers or organization charts in institutional websites. The constructed network is then used to guide the search for people or documents in response to user queries; a person can: i) ask to find the chain between himself/herself and a named individual; ii) search for an expert in a given topic and providing a maximum social radius (the number of “links” in the chain connecting the person performing the query with the expert); iii) request a list of documents written by people “close” to a given expert.

Yenta is a matchmaking system that helps people with similar interests to get in touch (Foner, 1997). Yenta agents do not query the web; instead, they scan user’s emails, Usenet posts and (possibly) documents in order to discover their users’ interests and hobbies. The idea is that many potentially interesting people do not publicly write and are consequently invisible to tools relying on public data. Collected data are then used to introduce users’ to each other. Considering that in the nineties web communities were built around the idea of common interests rather than personal acquaintance, the system was a truly distributed social networking system for the time.

Community Organizer is a system where agents help the users by gathering and exchanging information, visualizing contexts, and recommending or assisting their users in making a choice (Hattori et al., 1999). Each user has a personal agent and a set of additional community agents have the function of providing shared information, knowledge, or contexts within the community and act as mediators for informal communications between people. In particular, each personal agent acquires the user profile and visualizes potential communities around the user. The community agent collects the user profiles and maintains information on potential communities. Upon a request from a personal agent, the community agent first computes potential communities around the owner of the personal agent, and then sends the necessary

data (users in the potential communities and their relevance) to the personal agent.

Shine is a fully peer-to-peer framework for network community support (Yoshida et al., 2003). The framework also provides design guidelines and enables different applications to share program components and cooperate and features a peer-to-peer architecture through which personal agents can flexibly form communities where users can exchange information with peer agents. Essentially Shine is a middleware for collaborative workspaces especially tailored to implement various collaborative workspaces. Agents in Shine are goal-driven through plans: a plan is description of agent action rules. Multiple plans are executed concurrently in the plan execution module of each agent. Some plans are prepared to perform services of applications while other plans are provided by Shine to do fundamental or common tasks. A plan acts in response to external events, such as receiving a message from another agent, user input or notification about a change in the community.

MARS is a multi-agent referral system that finds experts on the basis of personal agents able to learn the user’s preferences and interests and able to build an expertise model of the other users on the basis of their responses (Yu & Singh, 2003). The expertise model is captured through a classical vector space model (Salton & McGill, 1983) and each personal agent maintains the models of its neighbors. In particular, the model is updated by a personal agent on the basis of the responses of its neighbors. The response can be an answer of its user or a referral: if the agent is reasonably confident about the expertise of its user matches the query, it directly answers; otherwise, it suggests a referral to another personal agent. Since the number of neighbors is bounded, some of them will be discarded to make place for new ones.

Blogracy is a peer-to-peer, anonymous and uncensorable social networking platform (Franchi et al., 2013). The architecture of the platform is modular and is built around a module for basic file sharing and DHT operations, possibly exploiting

an existing implementation, and another module providing a set of social services to the local user through a Web interface. Moreover, the platform provides two additional agent based modules respectively providing a set of pervasive services and a set of information retrieval and pushing services. In particular, the current prototype of Blogracy takes advantage of; i) Vuze (Vuze, 2016), a popular BitTorrent client implemented in Java and available as open source software, for implementing the file sharing and DHT operations, ii) Open Social (OpenSocial and Gadgets Specification Group, 2016), a set of APIs supporting the sharing of social data, for implementing the social services, and iii) JADE (Bellifemine et al., 2008), probably the most known agent development environment enabling the integration of agents and both knowledge and Internet-oriented technologies, for implementing the agent-based services.

MASCRM (Olszak, 2013) is a system based on a group of agents that independently acquire a number of important data necessary to manage the customer relationship by working on the top with a variety of social networks. Agents are able to communicate with each other and activate mutually. In particular there are able to collect a lot of data on the behaviour of the customers, their purchase preferences, etc. A prototype of the system has been experiment on the Facebook network a showed how agents work supports organizations to quickly respond to the opinions and attitudes of their current and future customers, and also to quickly assess the relevance of their marketing actions and decisions.

FURTHER RESEARCH DIRECTIONS

As illustrated above, while decentralized architectures can help in overcoming some of the problems of the most widespread centralized social networking platforms, multi-agent systems can be used for providing advanced social services on such a architectures. In particular,

multi-agent systems might become one of the most important means for the development of intelligent services for social networks and for coordinating the activities of its users. However, a lot of work is necessary for updating and experiment the coordination, knowledge management, and learning capabilities provided by multi-agent systems for the development of distributed services for helping the members in their activities and for, when will be necessary, using agents as delegate of some members for exchanging information and performing tasks.

CONCLUSION

Social networking sites are deeply changing the face of the Web, but their architecture might be improved. In fact, such systems utilize a traditional client-server architecture that relegates all the information in central servers. Although this approach supports highly mobile user access since users can log-in from any web browser, it also presents many drawbacks, e.g., lack of privacy, lack of anonymity, risks of censorship and operating costs. The integration between peer-to-peer technologies and multi-agent systems may be used for developing social networks that do not present the previous drawbacks. Moreover, the use of m multi-agent systems is the right solution to offer strong coordination techniques to the users of social networks and provide them more sophisticated and usable services.

KEY TERMS AND DEFINITIONS

Anonymity: State of being unknown or unacknowledged to the others.

Censorship: Modification or suppression of speech or other public communication which may

be considered objectionable, harmful, sensitive, or inconvenient as determined by a controlling body.

Multi-Agent System: A loosely coupled network of software agents that interact to solve problems that are beyond the individual capacities or knowledge of each software agent.

Peer-to-Peer System: A network based system in which each node can act as both client and server for the other ones of the system.

Privacy: The right to be secluded from the presence or view of others.

Social Networking System: A network based system facilitating the building of social networks.

Software Agent: A computer program that is situated in some environment and capable of autonomous action in order to meet its design objectives.

Aspects of Various Community Detection Algorithms in Social Network Analysis

St. Thomas' College of Engineering and Technology, India

INTRODUCTION

The 21st century is dominated by social media. Social networking websites like Facebook, Twitter and Myspace connect millions of people from all corners of the world. As a result, the global community is growing at a fast pace with new connections being forged every second. Businesses, government corporations and other organizations are relying increasingly on online networking in order to promote products, conduct surveys and target specific audiences. The immense importance of social media has catalyzed research in social network analysis, a field that had gained prominence in the mid '90s. Social network analysis involves the detection of communities or closely connected groups of individuals, studying the characteristic patterns associated with these communities, identifying important "key" actors in these networks and finally studying the overall behavior associated with people in the network.

BACKGROUND

Community detection in social networks is one of the most important areas of social network analysis. The most widely accepted definition of a community is a closely connected group of individuals with sparse connections to individuals belonging to other communities. With this definition in mind several algorithms have been implemented which serve to identify community structure in social networks.

Algorithms such as those proposed by Kernighan (1970) are traditional graph partitioning algorithms which use clustering techniques like *k*-means (MacQueen, 1967) to form graph clusters and can, therefore, be applied on social networks. The problem with these algorithms is that they can only find either a fixed number of communities or community clusters of a certain size, both of which may not really be the best case for real-world scenarios.

A very popular algorithm was developed by Girvan and Newman (2002) and uses a divisive technique in which edges are constantly removed to split a social network into smaller and smaller component networks. This technique gives rise to the natural community structure inherent in the network which can be represented through a community hierarchy. However, certain issues such as time complexity prompted one of the authors to devise an entirely new approach to detect community structure by optimizing a function known as *modularity* (Newman, 2004). This technique paved the way for a number of subsequent algorithms that collectively constitute the class of modularity-optimization algorithms. These include an improvement on Newman's fast algorithm (Clauset, Newman, & Moore, 2004) and an effort to improve community quality by balancing the communities detected by the CNM method (Wakita, & Tsurumi, 2007). The Louvain method (Blondel, Guillaume, Lambiotte, & Lefebvre, 2008) is, perhaps, one of the most popular greedy modularity-optimization algorithms which

DOI: 10.4018/978-1-5225-2255-3.ch603

is modelled on Newman's original modularity-based algorithm.

Further research developments led to the idea that community structure may not consist of just well-defined “crisp” clusters; rather, most real-world social networks contain communities that naturally overlap to a certain extent. Overlapping community detection algorithms serve to identify this natural community structure and either allocate the overlapping nodes to a single “best-fit” community through modularity optimization (Berti, Sperduti, & Burattin, 2014) or preserve the overlapping structure through the use of fuzzy membership functions (Kundu & Pal, 2015b).

COMMUNITY DETECTION ALGORITHMS: NEW AND OLD

Traditional View of Communities in Social Networks

Most community detection algorithms consider a model in which each individual in a network belongs to a single community. The individuals

in this community will have many connections with each other but will have a minimal number of connections to individuals belonging to other communities. In fact, this very phenomenon is exploited by nearly all of the community detection algorithms prevalent in social network analysis.

Overlapping Communities in Social Networks

Contrary to the traditional community model mentioned above, many recent research developments deal with more realistic models in which multiple communities may be assigned to an individual. In real world social networks, it is only natural for an individual to be a part of several communities simultaneously. For example, a student may be part of his/her study group consisting of close friends, and at the same time belong to the school's debate team which is an entirely different community. Many community detection algorithms fail to take this relevant aspect into consideration and are, hence, limited in their approach. The newer models, therefore, describe what are known as “overlapping” communities.

Figure 1. A graph representing the Dolphin Social Network: lines indicate edges and circles indicate vertices

Algorithms pertaining to both the models described above will be discussed shortly, but first some terminology that will be used throughout this article, along with their formal definitions, will be described below.

Terminology

1. **Graph:** A graph is a network of nodes and their interconnections. Each node in the graph is known as a vertex and each connection between two vertices is known as an edge (or link).
2. **Social Network:** A social network is a set of individuals that are interconnected in some manner. The criteria for the interconnections may vary: for example, a link in one network may be formed between two individuals if they are friends, while in another network a link may constitute the presence of a common interest or activity. Formally, a social network may be represented by a graph $G(V, E)$, where V is the set of vertices (individuals) and E is the set of edges. Figure 1 depicts a social network represented by a graph.
3. **Community:** A community is a subset of nodes in a social network that have dense connections between them and which are sparsely connected to nodes belonging to other communities.
4. **Edge Betweenness:** The betweenness of an edge (Girvan & Newman, 2002) is the number of shortest paths between vertices that contain the edge.
5. **Modularity:** Modularity (Newman, 2004) is a measure of the quality of community partitions formed by an algorithm. It is the difference between the actual density of intra-community edges and the corresponding connections in a random network possessing the same degree distribution as that of the actual network. The measure was given by:

$$Q = \sum_i \left(e_{ii} - a_i^2 \right) \quad (1)$$

where, e_{ij} is the number of edges connecting nodes in community i to those in community j , and a_i is the total number of edges that have one end in community i .

Equation 1 was extended to accommodate weighted graphs in (Blondel, Guillaume, Lambiotte, & Lefebvre, 2008):

$$Q = \frac{1}{2m} \sum_{i,j} \left[A_{ij} - \frac{k_i k_j}{2m} \right] \delta(c_i, c_j) \quad (2)$$

where, A_{ij} is the weight of the edge between vertices i and j , k_i is the total weight of all edges linked to i , c_i is the community to which i is assigned and $\delta(c_i, c_j)$ is 1 when both i and j belong to the same community and is 0 otherwise. The total weight of all edges in the network is m , where

$$m = \frac{1}{2} \sum_{i,j} A_{ij}.$$

6. **Role Players:** Role players are important nodes in a social network. They perform unique functions such as connecting individuals belonging to different communities or being a central player in an important activity.
7. **Granule:** A granule (Zadeh, 1997) is a collection of similar, indistinguishable objects that can be treated as an independent unit. In a social network, a granule may be denoted by A_c indicating that it is represented by a center vertex c . A node's membership in the granule is given by its relationship with c which is usually a distance function. The set of all granules may be represented as:

$$Gr = \left\{ A_c \mid \forall c \in C, \sum_{v \in V} \widetilde{\mu}_c(v) / v \right\} \quad (3)$$

where, $\widetilde{\mu}_c(v) = \frac{\mu_c(v)}{\sum_{i \in C} \mu_i(v)}$ and $\mu_c(v)$ is the

membership function of node v in the granule represented by c .

8. **Embeddedness:** Embeddedness (Kundu & Pal, 2015a) is the extent to which a pair of granules overlap. If the granules are represented by centers a and b respectively, then the embeddedness is denoted by $\varepsilon(a, b)$ and is nothing but the cardinality of the intersection of the granules:

$$\varepsilon(a, b) = |A_a \cap A_b| = \sum_{v \in V} \min \left(\left(\widetilde{\mu}_a(v), \widetilde{\mu}_b(v) \right) \right) \quad (4)$$

The Girvan-Newman Algorithm

The Girvan-Newman algorithm (Girvan & Newman, 2002) is one of the oldest and most popular community detection algorithms that have been developed. It had, at its core, the concept of betweenness which was used to partition the graph, i.e. the social network, into several communities. The algorithm consists of three simple steps:

1. **Look for the Edge with the Highest Betweenness:** As defined in the previous section, betweenness measures the importance of an edge in terms of the highest volume of ‘traffic’ it conducts. An edge with high betweenness indicates that the edge serves as an important bridge between nodes of different communities. Therefore, removing this edge would most probably separate the communities that it connects or ‘bridges’. With this concept in mind, Girvan and Newman proposed to detect the edge with the highest betweenness and remove it. If multiple edges have the same highest betweenness, all of them are removed. This step results in a possible partition of the graph into a number of initial communities.
2. **Recalculating the Betweenness:** After the first step the betweenness of all the remaining edges in the partitioned graph are recalculated. This is due to the fact that the removal of edges in the previous step will

obviously alter the flow of traffic among the newly formed graph components.

3. **Repeat:** With the new partitioned graph and betweenness values, repeat steps 1 and 2. The repeated application of these steps will break the graph into smaller and smaller components. This process is carried out until no further edges remain in the graph.

The Girvan-Newman algorithm decomposes the social network into a hierarchical structure with each level of the structure containing a set of communities nested within the community set of the previous level. Therefore, with this algorithm, one can observe the structural breakdown of the social network at each point of an iteration of the algorithm. The Girvan-Newman method works well for moderately sized graphs containing up to a few thousand nodes (Newman, 2004) but is less effective for larger networks due to the large computational complexity involved in re-computing the betweenness values during each iteration.

NEWMAN’S FAST ALGORITHM

In 2003, Newman (2004) proposed a more time-efficient method for detecting communities. His algorithm made use of his original concept of modularity which is defined in Equation 1. Newman’s algorithm is an entirely greedy approach that is implemented to address the pitfalls of the Girvan-Newman algorithm. Apart from the computational complexity involved in the Girvan-Newman algorithm, another aspect that the authors had failed to address was the formation of *meaningful* communities. While it is true that the algorithm detects community structure effectively, it does not include any metric for measuring the actual quality of the detected communities. In order to address this issue, Newman proposed to use modularity both as a qualitative measure as well as to find the communities faster. Newman argued that the modularity could be optimized

over all possible community divisions in order to obtain the best fit. Furthermore, the optimization could be done using a greedy approach to reduce the time complexity involved.

Initially, each node in the graph belongs to its own community, i.e. if there are n nodes then the number of communities will also be n . Communities are then joined together in pairs and the pairs that produce the greatest increase or smallest decrease in modularity are finally merged together. This process continues until all the nodes are eventually merged into a single community. The result is a hierarchical structure of communities in which each level contains a larger set of communities than its parent level. An important point to remember is that, when joining communities, only those pairs that have edges between themselves are to be considered as communities that are not connected by edges will never increase the modularity. Again, the change in modularity can always be calculated in constant time making the algorithm much faster than the previous one. Newman acknowledged that the local optimization feature could possibly lead to a decrease in the quality of communities detected as opposed to the non-local nature of the Girvan-Newman algorithm but emphasized the fact that while the latter algorithm is computationally very expensive for large networks, the former would be able to provide a decent community structure in considerably less time.

THE LOUVAIN ALGORITHM

The Louvain community detection algorithm (Blondel, Guillaume, Lambiotte, & Lefebvre, 2008) is a heuristic algorithm that uses modularity (as defined in Equation 2) as a metric for gauging the effectiveness of the detected communities. The algorithm is primarily aimed at detecting communities in large social networks in a relatively short span of time. The Louvain algorithm consists of a greedy “iterative stage” and a “coarse graining” stage.

1. **Iterative Stage:** In this stage, the change in modularity is noted when a particular node i is moved out of its own community and into the community of one of its neighbors. The changes are observed for each neighbor of i . Node i is finally moved into that community for which the change is maximum as well as positive. In the event that the maximum modularity change is negative or 0, the node i will remain confined to its own community. The process is repeated for every other node in the network. After all the nodes have been considered, the entire stage is applied iteratively to the network until no further modularity change is possible. In this manner, the iterative stage seeks to find the local maxima of the modularity obtainable in the network.
2. **Coarse Graining:** In the coarse graining stage, a new network is constructed by taking each community detected in the iterative stage as a single node. For the sake of clarity, the nodes in the old network will be referred to as vertices. An edge between two nodes in this new network is the sum of weights of the interconnections between vertices belonging to the community represented by the first node and those belonging to the community represented by the second node. Of course, by this same logic, there will also exist self-loops whose weights are equal to the sum of the *intra*-connections between vertices belonging to the respective communities represented by the nodes in the new network. The newly constructed network is then passed through the iterative stage which will detect a set of communities pertaining to the new network information.

The iterative and coarse graining stages are repeated until no further modularity change is possible. One can easily see by now that the size of data being processed during the iterative stage drastically reduces with each coarse graining process. Thus, this algorithm is extremely

effective when applied to large network datasets consisting of more than a million nodes. As in the algorithm developed by Newman (2004), one can visualize the community hierarchy detected by the two stages.

OVERLAPPING NODE DETECTION TO IMPROVE COMMUNITY CLUSTERING

Berti, Sperduti, and Burattin (2014) believed that the detection of overlapping nodes that belong to multiple communities is the key to detecting important role players in the network. These nodes bridge communities together and may, therefore, be strong “communicators” that connect individuals belonging to diverse groups. To achieve this end the authors proposed a new measure known as *cuttability* which helps in determining whether a node is an overlapping one or not. If we consider an edge (i, j) , the cuttability of this edge can be defined as follows:

$$cut(i, j) = \min \left\{ \begin{array}{l} \sum_{(i,k) \in E, C(i)=C(k)} w_{i,k} - \sum_{(i,k) \in E, C(j)=C(k)} w_{i,k} \\ \sum_{(j,k) \in E, C(j)=C(k)} w_{j,k} - \sum_{(j,k) \in E, C(i)=C(k)} w_{j,k} \end{array} \right\} \quad (5)$$

From the formula above, it can be easily seen that if both nodes i and j of a given edge belong to the same community, then the cuttability of the edge will be 0. If the nodes belong to distinct communities, the cuttability will increase. As a result, the cuttability will indicate the extent to which a node lies between two communities and is, hence, likely to be an overlapping node. The term “cuttability” arises from the fact that overlapping nodes can be “cut away” or removed from the graph without affecting the overall consistency of the clustering. The cuttability of the entire graph is the sum of the cuttability of all its edges. The

algorithm proposed by the authors consists of the following four steps:

1. **Initial Clustering:** Here, the fast Louvain algorithm (Blondel, Guillaume, Lambiotte, & Lefebvre, 2008) is used to detect an initial set of community clusters in the network.
2. **Detecting the Overlapping Nodes:** Once the initial set of clusters is obtained, the overlapping nodes are detected. Each node is checked by considering its actual community and the set of its adjacent communities. The node is assigned to each of its adjacent communities in turn and the change in cuttability is measured; at any point, if the change is positive then the node is an overlapping node.
3. **Re-clustering on Removal of Overlapping Nodes:** The set of detected overlapping nodes is then removed from the graph and another set of clusters is obtained from the reduced graph. This step once again uses the Louvain algorithm to quickly detect the clusters and the final modularity is measured.
4. **Adding back the Nodes to Maximize Modularity:** Finally, the overlapping nodes are added back to the reduced graph in such a way as to maximize the modularity. Steps 2 – 4 can be iterated until the modularity cannot be increased any further.

Through this approach, it may so happen that nodes which were overlapping nodes in a previous step cease to overlap in a later step due to formation of a better community structure. On the other hand, subsequent iterations may give rise to new overlapping nodes and, even more interestingly, some nodes may be persistent and remain as overlapping nodes throughout the process. These nodes may be regarded as truly overlapping in that they actually do belong to multiple communities even though they are finally assigned to a single community.

FUZZY – ROUGH COMMUNITIES IN FUZZY GRANULAR SOCIAL NETWORKS (FRC – FGSN)

The FRC – FGSN (Kundu & Pal, 2015b) model is a new approach towards detecting communities in overlapping networks. It considers the possibility that nodes may belong to a number of communities with varying degrees of membership. Furthermore, some nodes may not belong to any community at all and will thus be considered as ‘orphan nodes’. The model may be described in two parts:

1. **Fuzzy Granular Social Networks:** The Fuzzy Granular Social Network (FGSN) model (Kundu & Pal, 2015a) represents a social network in terms of ‘granules’. The concept of granularity helps model large-scale social networks in terms of a much smaller number of granules. Each node in the network will have a membership value associated with each granule. Of course, the value is dictated by a membership function that results in a value ranging from 0 (not a member) to 1 (completely a member). Any number in the interval (0, 1) signifies partial membership in a granule. This is, thus, a ‘fuzzy’ membership (Zadeh, 1965) as opposed to the ‘crisp’ membership values of 0 and 1 that are normally encountered. Furthermore, the membership values are normalized so as to gain a better idea of the ‘degree’ of membership of a node to a particular granule.
2. **Fuzzy Rough Communities:** The FGSN model is then analyzed for the detection of communities. There are two concepts that come into play here: embeddedness (defined in Equation 4) and θ – cores. θ – cores are merely those granules whose granular degree is greater than a certain constant θ . This value is generally set equal to the average granular degree in the FGSN. In the Fuzzy Rough Community (FRC) detection

method, all θ – cores are initially computed. Next, all community-reachable θ – cores are grouped together, and separated from the θ – core pool, to form individual communities (community-reachable θ – cores are those θ – cores for which the granule representative of one θ – core lies in the neighborhood (or support set) of the other). Also, all θ – cores of a community must have a mutual normalized embeddedness greater than a certain pre-defined constant $\in$. The communities that have so far been detected are merely in terms of granules. What is required, however, are communities that consists of only vertices and it is here that the concept of Rough Sets (Pawlak, 1982) comes into play. Since the communities are not well-defined, they can be represented as rough sets, each with their own lower and upper approximations. The lower approximation of a community will contain all those nodes which definitely belong only to that community and no other community. The upper approximation contains the lower approximation as well as nodes that belong to both the community in question as well as to other communities:

$$L(C_i) = \{x \mid x \in \text{Support}(A_p) \text{ and } x \notin \text{Support}(A_q)\}; \\ \forall A_p \in C_i, A_q \in C_j \ i \neq j \quad (6)$$

$$U(C_i) = \{x \mid x \in \text{Support}(A_p); \forall A_p \in C_i\} \quad (7)$$

Thus, the membership function for a node in a community C_i is defined as:

$$\delta_{C_i}(x, r) = \begin{cases} 1 & \text{if } x \in C_i \\ \sum_{c \in C_i} \widetilde{\mu}_c(x, r) & \text{if } x \in L(C_i) \setminus U(C_i) \\ 0 & \text{otherwise} \end{cases} \quad (8)$$

GRANLOUV: A PROPOSED COMMUNITY DETECTION ALGORITHM

In a previous work (Dillen & Chakraborty, 2015), the authors had proposed a novel algorithm for community detection. This algorithm, coined as *GranLouv*, was inspired by two of the algorithms mentioned above, namely, the Louvain method of community detection and the Fuzzy Granular Social Network model. There are three basic features associated with this algorithm:

1. **Formation of a Granular Adjacency Matrix:** The network is initially modeled in the FGSN domain by considering a set of granule centers and assigning the node memberships to these granules. The centers considered are those nodes in the original network whose degree is greater than the average degree of the network. The granule radius is taken to be equal to the network diameter. Once the FGSN is constructed, a new granular adjacency matrix is formed. An edge between two granules in this network bears a weight equal to the embeddedness (Equation 4) between the said granules. This would, thus, imply the existence of self-loops in the new network as well. In this case, the self-loop's weight will be the same as the cardinality of the granule with which it is associated.
2. **Applying the Louvain Algorithm on the Granular Matrix:** The granular adjacency matrix thus formed is then fed as input to the Louvain algorithm. The algorithm will detect communities in this 'network' which will be referred to as granular communities. These communities serve as a basis for the final step.
3. **Final Community Detection:** In the final detection stage, fuzzy rough communities are first detected in the network using the properties of lower and upper approximation in FGSN networks described in Equation 8. After this, all vertices are assigned to their

final communities: each vertex will possess a membership of 1 (i.e. complete membership) in the community for which its fuzzy membership is maximum. It will possess a membership of 0 in all the other remaining communities.

Application of *GranLouv*

The *GranLouv* algorithm was tested on three real-world social networks: the Dolphin Social Network (Lusseau, Schneider, Boisseau, Haase, Slooten, & Dawson, 2003), the Les Misérables Social Network (Knuth, 1994) and the American College Football Social Network (Girvan & Newman, 2002). The algorithm achieved a modularity of 0.509, 0.534 and 0.599 respectively in each of the three cases which is quite comparable to other algorithms employing the use of modularity. The results are depicted graphically in Figure 2, Figure 3, and Figure 4 as well as in Table 1, Table 2 and Table 3 respectively.

Table 1. Modularity detected by algorithms on the Dolphin Social Network

Serial No.	Algorithm	Modularity
1.	Louvain	0.518
2.	GranLouv	0.509

Table 2. Modularity detected by algorithms on the Les Misérables Social Network

Serial No.	Algorithm	Modularity
1.	Newman and Girvan (2004)	0.540
2.	Louvain	0.555
3.	GranLouv	0.534

Table 3. Modularity detected by algorithms on the American College Football Social Network

Serial No.	Algorithm	Modularity
1.	Girvan and Newman (2002)	0.601
2.	Louvain	0.604
3.	GranLouv	0.599

FUTURE RESEARCH DIRECTIONS

Although the granule centers in GranLouv are chosen on the basis of vertex degree, this practice may not necessarily be the best way to do so as it takes only one factor into consideration, i.e. the degree, and so fails to properly and holistically select the nodes which have a higher tendency to form clusters or granules around themselves. This problem must be addressed effectively as granule center selection poses a level of difficulty when the networks consist of a very large number of nodes. It is definitely not feasible to select all nodes in the network as centers as this would go against the actual idea behind using a granular model in the first place, which is to reduce the amount of redundant information in the network and ease the computation process.

Another aspect that must be taken into consideration is the absence of overlapping communities using GranLouv. This problem may be addressed

by changing the modularity function to account for overlapping communities as well instead of only crisp community sets.

Finally, attention must be drawn to the fact that granules are assumed to be circular in nature with a predefined radius set by the programmer. However, a granule should be allowed to assume any arbitrary shape in order to realistically capture information in the network. Therefore, there is much scope for research work which can properly and efficiently consider granules with any shape as opposed to the strict and inflexible one that has been proposed.

CONCLUSION

Social network analysis, and especially community detection, has a multitude of benefits. Through community detection, business organizations can use social network data to determine appropriate

target audiences for their products and selectively advertise to the target audience, thus increasing the probability of attracting potential buyers. Law enforcement agencies may also use social network analysis to identify potential or existing criminal organizations based on the connections of known criminals. Furthermore, “important” players in social networks may also be identified with a higher degree of accuracy through detection factors such as popularity (number of connections), behavior, and other pertinent features. Thus social network analysis plays an important role in economics, business intelligence and law enforcement, as well as other areas ranging from politics to information science. Research in this field could, therefore, significantly address a number of problems in a world that is becoming increasingly globalized and interconnected at a rapid pace.

ACKNOWLEDGMENT

The authors wish to convey their thanks to Prof. Sankar Kumar Pal as well as Mr. S. Kundu from the Center for Soft Computing Research, Indian Statistical Institute, Kolkata, for their continued support and guidance provided during the conception of this paper.

KEY TERMS AND DEFINITIONS

Community: A community is a subset of nodes in a social network that have dense connections between them and which are sparsely connected to nodes belonging to other communities.

Edge Betweenness: The betweenness of an edge is the number of shortest paths between vertices that contain the edge.

Embeddedness: Embeddedness is the extent to which a pair of granules overlap.

Granule: A granule is a collection of similar, indistinguishable objects that can be treated as an independent unit.

Graph: A graph is a network of nodes, or vertices, and their interconnections, or edges.

Modularity: Modularity measures the quality of community partitions formed by an algorithm. It is the difference between the actual density of intra-community edges and the corresponding connections in a random network possessing the same degree distribution as that of the actual network.

Role Players: Role players are important nodes performing unique functions in a social network.

Social Network: A social network is a set of individuals that are interconnected through some relationship.

INTRODUCTION

Many researching works implement procedures to use web data and users generated content on critical situations management, or to notify relevant events (Wakefield, 2013). Every day millions of publications, where people describe their environment, and ideas about many interesting topics are done at social networks. From such publications, it is possible to acquire data related to the urban factors that concern most citizens, in order to improve the people's activities and conditions, and with a view to structure smart cities. Web publications that have coordinates or provide geographic information, can be considered as VGI.

The main purpose of this work, is to obtain useful information for a further traffic prediction procedure, by integrating and processing VGI and authoritative data. The VGI data is collected from a social network, where participants are considered as intelligent sensors, which constantly communicate the environment changes they perceive; such reports are influenced by the people context.

Two of the main advantages of VGI, are its continuously updated data, and the easily data consultation. Such kind of source has not been deeply studied, most of the time its social characteristics have been analyzed over its technological usages.

The present approach makes use of VGI and authoritative data sources, to extract, analyze, classify and geocode data related to the traffic in the study area. The case of study is Mexico City, the largest metropolitan area in America, and the largest Spanish-speaking city in the world (Zimmerman, 2015).

The social network consulted is Twitter, also a RSS service is considered. In the analysis stage, a text mining and a recovery information processes are applied over the short texts, extracted from the social network and from the rss service, with a view to identify the traffic events described on the posts; on the classification stage, a Naïve Bayes algorithm is trained to classify the traffic events. The geocoding process is done through the use of the methodology proposed by Salazar et al. (2016). The events and the authoritative data, are related with the purpose to establish links, between the streets and the business located on the area where the traffic is presented; also a probabilistic analysis is applied. Finally, the events and the authoritative data are mapped to visualize the traffic distribution.

The paper is organized as follows: first the background of the work is shown, below the data treatment is described; then, solutions and recommendations are done; after the future research directions and conclusions are presented; finally, the additional readings are mentioned.

BACKGROUND

User generated content (UGC) is any publication on internet, done by users of web services such as blogs, wikis, forums, social networks, podcast and chats. It is used in many applications, including: researches, information and news spread, problems processing, disaster management, and collaborative mapping. UGC has originated some other concepts, volunteered geographic information (VGI) and crowdsourcing are two of them (Chard, 2015).

Crowdsourcing is the process of getting ideas, information, or work done, from a group of interested people; it has been a recurrent data and services source for some businesses and researches (Chard, 2015). Mobile devices as smartphones, mobile GPS, cartographic applications and social networks, make crowdsourcing possible.

According to Wen Lin (2013), VGI is composed of volunteered information generated by users, who have not a geographic specialized knowledge, but are interested on provide data with geographic characteristics; such data are employed on many web services as Open Street Map (OSM), WikiMapia, Google Maps, among others. This association between VGI and web services are the GeoWeb basis.

VGI makes possible the generation of new spatial information usages, such as collaborative mapping, georeferenced content, network vectorization, and collective ranking of places (Gouveia & Fonseca, 2008; Elwood, 2013; Sui, 2012; Goodchild, 2007). There exist web services that invite people to provide personal information, their location, or some other geospatial information, such as landmarks, points of interest (POI), and street segments; with the purpose to increment their data repositories, and make them available for further analysis. OSM, Foursquare, and Twitter are some of those web services (Kunze, 2015).

Kunze (2015), proposes a VGI integration process, to generate estimation models of dwelling occupancy. In his approach, OSM and topographic data from Dresden city are used. When

working with data from many spatial data sources, it is needed to correctly integrate such data on a GIS environment, and to consider some specific features, as the data precision, and the reference system applied over them (Flowerdew, 1991).

Most of the internet users, are part of the social networks; according with previous investigations 70% of them, access to internet by using mobile devices; and 73.4% do it through a computer (Castells, 2010).

Nowadays, internet users are interested on describe their environment, or give information about the events they perceive; on their publications people describe physical aspects of their surroundings, as the traffic or pollution situation, the security degree they consider appropriate for their neighborhood, socio-politic events, and some other topics of interest; also, they provide metadata such as coordinates, URL's, among others (Fleming, 2014).

User generated content published on social networks and VGI sources, has an explicit semantic value, since the content has been produced by people interested on provide their data for further analysis, unlike the other web content generated by people without a specific purpose (Resch, 2015).

Considering people as sensors, gives a wide variety of heterogeneous data, to researches that study the human behavior or the city dynamics, through the analysis of VGI and UGC data. The people's point of view is different from one person to another, and it is influenced by the person's living conditions, activities, education, ideas, and the geographic area where he or she lives (Resch, 2015).

DATA TREATMENT TO DETECT TRAFFIC EVENTS ON TEXTS

The present approach has been designed to obtain information about the traffic situation in the study area, by analyzing and processing VGI data. The proposed methodology, consist on 5 stages: the first, is the data acquisition; the second, are

Figure 1. Data acquisition from a social network to describe the urban traffic situation methodology stages

a text mining and a recovery process, to obtain data related to traffic events; the third, is the data classification; the fourth, is the data geocoding; and the fifth, is a statistical analysis. On Figure 1, a diagram shows the methodology stages.

The social network consulted for this research is Twitter; it is one of the most used micro blog services, at present has more than 500 million

users. On its web site, people post their ideas, on short texts called tweets, which have a limit of 180 characters (Bernstein, 2013). The tweets considered as relevant for this approach, are those which describe the traffic situation or traffic events occurred on the study area.

This work has been oriented to detect traffic information published by people; an advantage

of the approach is its flexibility, since it could be used to extract information related to some other urban topics, in order to improve human life.

Data Acquisition

To extract the short texts from Twitter, an API of basic transmission is used on a code script to randomly extract, the 1% of tweets published on the study area. The tweets are continuously extracted, since the API can not to have access to tweets published one week before the consultation date.

The short texts, are obtained from specific Twitter accounts, which main purpose is to notify the traffic on the study area. The Twitter profiles monitored are @*trafico889*, @*dftrafico* and @*MexicoTrafico*.

The collected tweets and their metadata, are stored on a table named *traffic_data*; the features considered are the tweet's publication date and time, its text, and its coordinates (in case they have been published). Some Twitter service studies, have shown that only 3% of the tweets have the coordinates of the the place where they were posted, and only 17% of the short texts have relevant information about the place of publication (Burton, 2012).

To extract the information from the rss service, a PHP script was developed to collect the news related to traffic on the study area, that have been published by some of the most important local journals: *Reforma*, *El Universal* and *La Jornada*. The text, date and time of publication, were extracted from the news collected, and then stored on a table named *rss_service*. Both *rss_service* and *traffic_data* tables belong to the *traffic_situation* database.

Information Recovery

Once the tweets and rss texts have been collected, is needed to extract from the texts, the information related to the traffic situation and to the traffic events. The texts stored on the *rss_service* and *traffic_data* tables, are written in Spanish

language. In order to manipulate such texts it is necessary to apply a text mining process and a recovery information procedure.

The stop words, are all the common words on a language, such as prepositions, connectors, and articles, that do not provide relevant information to the texts (Sidorov, 2014).

On the text mining process, it is necessary to remove the stop words from the texts; also, the special characters used on the Spanish language (':,;.\$%`!¿?/*...') are deleted. After this process, texts are ready to be treated by more complex computing procedures.

The information recovery process, consist on identify the words related to the traffic on texts; this is done by a programmed script, that identifies on each tweet or rss text, the words related to the traffic and the number of times that they appear.

The identified words are grouped, according to the event to which they refer, into five classes: *favorable* and *traffic*, define the situation of the vehicles movement through the streets; *accident* and *closure*, describe traffic events; *rule*, when the text has information about road rules; and *unidentified*, when none of the text's words are related to traffic events.

Data Classification

On this section, the rss texts, and the tweets text are indistinctly called *texts*, in order to simplify the explanation. The classification process described below, is independently applied over the *rss_service* and *traffic_data* table's registries.

To classify the texts, the Naïve Bayes algorithm has been chosen; it is a machine learning algorithm based on the Bayes conditional probability theorem, which main purpose is, to calculate the probability for a document, to belong to a determined class, in case that it contains a specific word (Scharkow, 2013). Naive Bayes, assumes that a feature's presence or absence, is not related to any other feature's presence or absence. The algorithm, has been used as a standard for text classification and

spam filters; its main advantage is, that it is good working with big amounts of data, and needs few data to determine class parameters (Lantz, 2013).

Naïve Bayes requires a training process, where the algorithm is applied over a training dataset, to create probabilistic tables that let it know the differences between the proposed classes, and the kind of element that is being treating.

To create the training corpus, the third part of the texts was classified, by using an algorithm that searches on each registries' text, the words related to each proposed class, and assigns to the registry a class label according to the major number of class' words founded. The class label is stored on the field *event_class* of the *rss_service* and *traffic_data* tables. The third part of the texts with a defined label class are named *training corpus*, meanwhile the two third parts without label are called *test corpus*.

The Naïve Bayes algorithm develops the following steps; first, from the training corpus extracts the *event_class* label of each registry and factorizes it, it means that represents such class label with a number; and then, a data dictionary is created to save all the words that compose the texts. Each word, acts as a key on the dictionary, and its value is the number of times the word was founded on the entirely training corpus, this is done by comparing each registry's text of the *rss_service* and *traffic_data* tables, with the words in the dictionary; if there is a word on a text that does not appear on the data dictionary, it is added as a new key.

Since texts have different lengths, it is needed to homogenize their longitudes, to make them useful for the machine learning's training. For that purpose, a vector is created for each text, each vector's position represents a dictionary's word, catalogued in the same way as in the dictionary; the value of each position, is the number of times the word appears on the treated text. In case that a word does not belongs to the text, its value is zero. Every text (from the tweets or the rss messages), has a representing vector.

Once the vectors have been structured and the classes have been defined, the Naïve Bayes, algorithm calculates the probability for each dictionary's word to belong to any of the defined classes, by counting the times that an specific word appeared on each class, and dividing that number, between the total words on the class $P(B)$. Then, it calculates the probability that the training registries have been correctly classified, based on the words present in them, and the calculated words' probabilities. The process is related to the Bayes theorem shown on Equation 1, where B is the word founded on the registry, A_i is the dependent event (the label of the class we are analyzing), $P(B)$ is the marginal probability of the word, $P(A_i)$ is the prior probability of the class A_i , $P(B|A_i)$ is the likelihood of word B in the class A_i , and $P(A_i|B)$ is the posterior probability of classify the registry on the A_i class, given that the founded word was B .

$$P(A_i|B) = \frac{P(B|A_i)P(A_i)}{P(B)} \quad (1)$$

After the training process, is time to Naïve Bayes learning. When a new registry is being analyzed, the algorithm calculates its posterior probability, in order to determine the appropriate class for it, taking into account the values stored on the text's vector. The *posterior probability* for a vector to belong to each of the classes, is calculated considering the presence probability computed on the training stage for each vector's word (*marginal probability*), and the words absence probability. Then, the *posterior probabilities* are added, the result is called *class probabilities*, as shown in Equation 2; the probability for the vector to belong to a certain class, is calculated by dividing the *conditional probability* between the *class probabilities* calculated previously, as shown in Equation 3. The number of classes is 5, as defined on the information recovery process.

$$class\ probabilities = \sum_{j=1}^5 P \left(\begin{matrix} Class\ j\ |\ -\ probability\ of\ words \\ presence\ or\ absense - \end{matrix} \right) \quad (2)$$

$$P(vector \in Class\ i) = \frac{P \left(\begin{matrix} Class\ i\ |\ -\ probability\ of\ words \\ presence\ or\ absense - \end{matrix} \right)}{class\ probabilities}, \forall i \in [1,5] \quad (3)$$

The class chosen for the vector is the one with the highest numeric value. After the learning process, Naïve Bayes is ready to classify the test data. The classification process follows the next sequence: first, the texts of the test corpus are tokenized to search for new words to be added on the data dictionary, and to identify the number of each word repetitions in the corpus; then the words frequencies are calculated. After that, a vector with the same length as the dictionary is created for each text; the conditional and class probabilities for each vector are calculated; and finally, the highest probability for each vector to be part of a class is selected, in order to assign it a correct class label. The class labels are stored on the *event_class* field, for any of the registries of the tables analyzed.

Data Geocoding

For the data geocoding, a gazetteer based on the methodology proposed by Salazar et al. (2016) has been used; the gazetteer is derived from *GeoNames*, and has 36,236 elements that represent Mexico City's streets with names written in Spanish, and abbreviations that describe the hierarchy of the roads. The gazetteer works with spatial dictionaries that represent the location of transport stations with points, the streets with

lines, and the location of monuments, buildings and some other landmarks with polygons.

On the geocoding methodology the text is analyzed, by identifying words which make reference to monuments, buildings, streets and avenues through the use of n-grams, bi-grams and tri-grams on it, by applying a recovery information process (Sidorov, 2014); once that the elements have been identified, a geospatial representation (point, line or polygon) defined on the spatial dictionaries, is assigned to them. By calculating the possible combinations of the geometric elements, the spatial relations between the detected elements are calculated ((line, line), (line, polygon), (line, point), (point, line), (point, point)), when the resultant relation is possible, the coordinates of the elements intersection, are chosen as the coordinates for the event described.

What the proposed approach does on this stage, is to apply the geocoding methodology of Salazar (2016) over the registries texts stored on the *rss_service* and *traffic_data* tables, in order to obtain its coordinates. The resultant coordinates are stocked on the fields *x_coordinate* and *y_coordinate* of the mentioned tables.

The *traffic_situation* database, has been structured on *Postgresql*, as shown on Figure 2. By using the spatial extension *Postgis*, the texts coordinates, are transformed into geometric points, to represent the events they describe, in the study area's map; such transformation is possible by applying the Postgis function *ST_GeomFromText*.

Statistical Analysis and Results

To make a better analysis of the classification and geocoding results, a statistical analysis was applied over the 5000 tweets and rss texts treated.

It was found that 32% of the processed texts, have information about accidents occurred on the roads; 62.98% describe the traffic situation, and from them, 14.24% describe a good circulation situation, meanwhile the 48.74% show problems for vehicles to move through the streets; 4.0% refer to streets closures; and only 1.02% of the texts, had

Figure 2. Tables from traffic_situation database

not enough information to be classified. On Figure 3, a circle graph shows the events proportion.

To have a better event's visualization, the points of each class were mapped on the study area. Here the authoritative data is used, to relate the classified and georeferenced traffic events, with the location of commercial businesses of the study area. The authoritative data is a shape file from the geography and statistics department in Mexico, each point in the shapefile, represents a commercial entity in the city, and provides infor-

mation such as the business schedule, commercial activity, and number of workers.

The used cartography belongs to Open Street Map; which lets to this approach make a relation between the VGI data from a mapping platform, and the VGI data from a social network. On Figure 4, a map with the OSM cartography shows the authoritative data (points), and buffers of 100 meters round the businesses, to detect the traffic events reported by citizens near to them. The information from the businesses makes possible to relate its commercial activity, and the number of traffic events detected.

Figure 3. Circle graph that shows the classified events proportions

SOLUTIONS AND RECOMMENDATIONS

The first problem this approach presented, was the texts geocoding. Since a few part of the short texts from the social network have coordinates, and most of the rss texts recovered have not the coordinates of the place where they were published, or of the event they describe, it was necessary to implement a geocoding process. One solution proposed, was using a basic gazetteer to search for the streets names on texts; the issue with this solution is, that it does not exists a complete Mexico's gazetteer, and that there are streets names in Mexico City,

Figure 4. Buffers created round authoritative data, to evaluate the number of traffic events, and its relation to the commercial activity of the represented place

related with names of people and places from other countries, such as Liverpool, Zurich, Benjamin Franklin, among others. When using this proposal, many short texts were geocoded at some other latitudes far from Mexico, as represented on Figure 5, where the street named *Berlin* in Mexico City was geocoded in Germany.

Looking for another solution, it was found that many researches use annotators to geocode tweets manually, this is one of the most accurate ways to geocode, but it is not easily scalable and requires more time and participants. The methodology proposed by Salazar (2016), was the most efficient for this investigation, since by an automatic

Figure 5. Coincidence between Mexico City streets names, and places out of the study area with the same name

Names coincidences that affect the correct data geocoding

Berlin street in Mexico City (study area)

Berlin City in Germany (not the study area)

process, the coordinates for the text were obtained with a good precision level.

Another issue, was the classification model election. Our approach was designed to use a machine learning algorithm, and by studying many tools, it was decided to apply the Naïve Bayes classification algorithm, due to the good results that it has reached by classifying texts such as e-mails and SMS. Naïve Bayes requires a training data set, to learn patterns and to be useful for further data classifications; such data set was classified manually. A recommendation for this approach is to use some other semi-classified machine learning algorithms, to classify the test corpus created by the present research, and make comparisons between the new results and the Naïve Bayes ones.

FUTURE RESEARCH DIRECTIONS

This methodology has been proved to extract information about the traffic on urban areas, with the study case in Mexico City, but it can be used to extract information about some other urban topics, as well as air pollution, floods, robbery, among others; the changes needed on the procedures, to treat other topics, must be done on the relevant words to be considered on the text mining and recovery information processes, and in the classification of the data from the training corpus. On the machine learning stage, the update is not necessary since the algorithm learns the interesting words from the texts, by calculating their probabilities of presence and absence.

The analysis of traffic has been done on this approach, with a view to provide classified traffic events descriptions with their coordinates to a further research, that studies the relation between traffic events in a city and models the behavior of traffic in urban areas by regression models.

CONCLUSION

The present approach, makes use of VGI and authoritative data, to represent and classify the traffic events on an urban area. The authoritative data are geometric points that represent the commercial businesses on the study area; the VGI information is acquired from Twitter messages and from rss services. The social network Twitter has been chosen because of its large number of members and the facility to extract information from it, by using a Twitter API.

The study area is Mexico City, one of the most populated and with more demographic density in America. Since the collected tweets belong to Mexican Twitter accounts, the short texts are written in Spanish language. After the extraction from tweets and rss, texts are stored on a database named *traffic_situation*, into two tables; then a text mining procedure, and an information recovery process are applied over the data to eliminate special Spanish characters, and to extract the words that describe events or situations related to the traffic on the study area.

The data set of tweets and rss texts, are partitioned into three. The identified traffic words in Spanish, such as *lento*, *accidente*, *cierre*, *avance* among others, are used to classify one data set partition, into five classes: *traffic*, *favorable*, *closure*, *accident* and *unidentified*; by using a words comparison method. Such classified partition is called training corpus.

To classify the other two partitions which compound the test corpus, Naïve Bayes a semi-supervised machine learning algorithm is used. The algorithm is trained with the classified texts, and calculates probability tables, in order to learn how to classify new texts based on the words that they contain or not; after the training process, the algorithm classifies the test corpus into the same five classes defined on the information recovery stage.

Despite some of the short texts from such microblogging service have the coordinates of the place where they were published, it is necessary to apply a geocoding process over the data, in order to know the coordinates of the place where the classified traffic event is being described.

When the classification and coordinates of the texts are known, geographic points are created to represent the events on the area's map, with a view to identify the places with more traffic, and its relation with the commercial businesses; a statistical analysis is also done, to know the proportion of each defined class.

The present approach collects, classifies and geocodes traffic events information, nevertheless, it could be useful in the acquisition and data treatment of many topics, or to analyze traffic on some other study areas.

KEY TERMS AND DEFINITIONS

Gazetteer: A geographical dictionary that contains information about socio-economic statistics and physical features of a geographic area.

Geocoding: The process to obtain coordinates from spatial reference data on texts, such as street names or landmarks.

Metadata: The data that contains some other data or labels it, to describe its content, such as coordinates or URL information.

Microblogging Service: A service to distribute content to a group of members by internet, such content could be short texts, small audios or video links.

RSS Service: A document used to publish frequently updated information, which includes text and metadata.

Social Network: A web platform where people shares interests, activities and establish social relations by virtual connections.

Traffic: The movement of people, vehicles or merchandise through the roads, it can be fluent or congested.

Communication Privacy Management and Mediated Communication

S

Debra L. Worthington

Margaret Fitch-Hauser
Auburn University, USA

INTRODUCTION

Sandra Petronio (1991) introduced communication privacy management theory (CPM) to explain how individuals control and reveal private information. While it was originally developed as an organizing principle for understanding disclosure in traditional social interactions, it has since been extended to a number of contexts, most recently to evolving communication technologies and social networking sites, including online blogging (e.g., Child & Agyeman-Budu, 2010; Child, Petronio, Agyeman-Budu, & Westermann, 2011), Facebook usage (e.g., De Wolf, Willaert & Pierson, 2014; Waters & Ackerman, 2011), and Twitter and Short Message Service (SMS) (e.g., Cho & Hung, 2011; Jin, 2013; Patil & Kobsa, 2004). CPM provides a set of theoretical tools to explore the intersection of technology and individual privacy in relationship management. Below privacy is defined, components of communication privacy management theory and their application to mediated communication are outlined, and areas of future research are presented.

BACKGROUND

Both a dynamic and dialectic process, the notion of privacy suggests that individuals regulate boundaries of disclosure, personal identity, and temporality (Palen & Dourish, 2003). More specifically, it refers to our ability to manage when, how, and

the extent to which our personal information is revealed to others (Westin, 1967).

When discussing the intersection of technology and privacy, people often focus on technical issues associated with technology use (see, for example, Boyles, Smith, & Madden, 2012). In reality, individuals focus significant attention on managing privacy in their online digital lives. CPM provides a means to better understand and explain how individuals use and communicate in online and mediated communication contexts (Child & Petronio, 2011).

COMMUNICATION PRIVACY MANAGEMENT THEORY

Originally developed for interpersonal contexts (Petronio, 1991), research associated with CPM initially focused on social and interpersonal interactions in areas such as family and health communication. (e.g., Petronio, 2006; Petronio & Caughlin, 2005; Petronio, Jones, Morr, 2003).

Petronio (2007) describes CPM theory as “an evidenced-based, applied theory construct to be translatable into practices” (p. 219). The CPM system rests on three elements – privacy ownership, privacy control and privacy turbulence. Eight axioms predict privacy practices (Petronio, 2013). The first two axioms are associated with privacy and the ownership of personal information. Axiom 1 proposes that individuals believe in private ownership of their personal information

and in their ability and right to share or protect that information from others. Axiom 2 predicts that when access to private information is granted to others, those gaining access become co-owners of the information, taking on the trust and responsibility that comes with co-ownership.

Axioms 3 – 6 are associated with privacy control. Petronio (2013) described privacy control as the regulating engine for determining the conditions of providing or denying access to private information. Thus, not only do individuals believe they are sole owners of their personal information (i.e., Axiom 1), but they also believe they alone control their personal privacy, even when that information is shared with others (Axiom 3). At the same time, how information is shared is based on the privacy rules individuals develop (Axiom 4). Core and catalyst criteria influence decisions on how and when rules are invoked. Core criteria are the most stable and predictable guidelines for privacy choices, while catalyst criteria result in privacy rule changes based on motivation and risk assessments.

Axiom 5 addresses how, once access to private information is shared with others, the original owner continues to maintain control by continued coordination and negotiation of privacy rules associated with third-party access (Petronio, 2013). However, ownership rights can be challenged when individuals manage multiple, often inter-related, privacy boundaries (e.g., can information revealed by a friend be shared with another mutual friend) (Petronio, 2002). Confidants fall into two categories – deliberate confidants purposely ask for information (e.g., bank employee and customer), while reluctant confidants receive unwanted private information (e.g., a third party present during a mobile phone exchange). Reluctant confidants may experience unwanted feelings of obligation and responsibility (Petronio & Reiersen, 2009). If the parties can reach a consensus about privacy rules, and accept the means by which they became deliberate confidants, then the confidant relationship can be effectively regulated.

The complications of collective co-ownership are seen in Axioms 6 and 7. Co-ownership leads to mutually agreed upon and practiced privacy boundaries where all members of the group can engage in sharing private information (Axiom 6, Petronio, 2013, p. 10). These group held privacy boundaries are regulated by decisions about who may divulge what information to whom and when. (Axiom 7, Petronio, 2013, p. 11). Thicker boundaries suggest that the coordinated rules of those collectively holding private information are relatively closed, while thinner boundaries are more permeable, resulting in information that is more accessible and open to third parties (Petronio & Reiersen, 2009). The original owner of the information and the confidant negotiate the level of access third parties may have, including the scope and extent of private information that can be shared.

The purpose of these boundaries is to govern who has control of and access to information as well as how to protect that information (Petronio, Sargent, Andea, Reganis, & Cichocki, 2004). People manage or coordinate privacy boundaries based on negotiation of privacy rules related to linkages, boundary permeability, and information ownership (Petronio, 2002). Privacy rules are both normative and situational and affected by a number of factors, including cultural expectations, individual motivations, risk-benefit assessments, gender, and the needs of the situation (Petronio, 2009). Importantly, multiple rules may be used during the boundary management process.

The final axiom, Axiom 8, addresses the area of privacy turbulence, and acknowledges that privacy regulation does, at times, fail and rules are broken. Privacy boundary turbulence often results from confidentiality breaches (i.e., privacy expectations of the original owner of information are not met by co-owners) (Petronio & Reiersen, 2009). Violations of confidentiality – discrepancy breaches of privacy, privacy ownership violations, and preemptive privacy control – can negatively affect the relationship of those involved.

APPLYING CPM TO MEDIATED COMMUNICATION CONTEXTS

The principles of CPM have been used to explain how individuals use social networking sites as well as emerging communication technologies. This section illustrates how CPM's principles and axioms can be and have been applied in these areas. The first principle of CPM asserts that individuals own their private information. In many ways, this norm was strengthened with the advent of mobile technology (Bergvik, 2004). For example, mobile phones have shifted from a location-based technology to person-linked devices. Today, they are viewed as a central element to individual identity and public presentation (Arminen, 2007; Campbell, 2008), and subsequently as private and personal property (Rosen, 2004; Häkkinen & Chatfield, 2005). This norm has become so well established that few individuals will answer another's cell phone in recognition that calls and texts are private belonging to the owner of the phone. The result is that incoming calls are viewed as private communication with the phone's owner even when the caller or receiver is in a public setting. Mobile phone users can manage privacy concerns by strategically choosing their method of communication (e.g., instant messaging, SMS, voice, etc.) (Worthington, Valikoski, Fitch-Hauser, Imhof, & Kim, 2012). Each means of communication comes with its own set of privacy concerns with some mediums implying greater ownership and having thicker boundaries than others. For example, Häkkinen and Chatfield (2005) found SMS messages are assigned greater privacy, and are seen as more confidential, than voice calls.

In online communication, individuals will sometimes treat public domain space as if it is private (Child & Agyeman-Budu, 2010; Child & Petronio, 2011). One consequence may be posting, tweeting, blogging or otherwise sharing information that results in follow-up measures to manage privacy (Axioms 3 & 7). Bloggers who remove or "scrub" a message from their blog have reevaluated the risk-benefit ratio of retaining a

message on their blog (Child, et al., 2011). Thus, blog scrubbing results from the recognition of potential privacy turbulence (Axiom 8) that may result from privacy violations. A number of factors may lead bloggers to change their regular privacy rules, among them impression management, safety, and relationship considerations (Child et al., 2011). Blogger perceptions of privacy appear to fall along a continuum ranging from those who are highly aware of privacy issues and proactively weigh the risks (the cautious blogger) to those who never worry about their privacy (high risk-taking bloggers). In these two cases, blog scrubbing will rarely occur. However, the normative blogger is cognizant of triggers and will adjust privacy rules to situational demands.

Axiom 2 predicts that when access to private information is granted to others, these gaining accesses become co-owners of the information, taking on the trust and responsibility that comes with co-ownership. Facebook postings are an example of information that individuals move across their privacy boundary to become collectively co-owned with Facebook friends (Child & Petronio, 2011). In such cases, there is a loss of individual control in favor of being social and interacting with others in their network (Bateman, Pike, & Butler, 2011; Child et al., 2011). These friends become authorized co-owners of the information. However, users who are more protective of their privacy may engage in a variety of strategies, including providing less information, making vague postings, and using coded language (Axiom 4; Child & Starcher, 2016; Child, Duck, Andrews, Butauski, & Petronio, 2015). There are a number of reasons for increased privacy concerns with Facebook and similar social networking sites. Users may be concerned with who they are interacting with or be worried about family members, romantic interests, colleagues, employers and others who may be engaging in mediated lurking (Child & Westermann, 2013; Child et al., 2015; Frampton & Child, 2013). Of course, users can reclaim privacy by deleting postings. Notably, they can also refuse to accept responsibility for

disclosures placed on them by others. This refusal can be seen when individuals delete comments or other information posted on their personal site by others (i.e., reluctant confidants, Axiom 5).

Related to social networking sites, De Wolf and colleagues (2014) suggest that just as individuals create personal boundaries, they also create group boundaries with others with whom they share information. Adequate feelings of control and privacy management reside with the group. Their study supports Petronio (2002) assertion that individuals must establish both individual and group privacy norms in order to have adequate management of privacy issues.

Finally, privacy perceptions differ across cultures and countries. For example, in a Malaysian study, Mohamed and Ahmad (2012) identified several reasons individuals are concerned with information privacy associated with technology, communication, and social networking sites. They note that a user's perception of the gravity of losing any kind of personal information leads to increased privacy behaviors. They also report that protective behavior use will increase when users find it easy to use security settings. In a study of the effect of cultural differences on mobile phone usage, Worthington et al. (2012) reported differences in user privacy concerns across the four countries they studied (Finland, Germany, South Korea, and the U.S.). For example, Finnish and U.S. respondents were more sensitive to the interaction between conversational topic and public location than South Korean and German participants.

FUTURE RESEARCH DIRECTIONS

Arguably, one of the strongest concerns individuals have with communication technology is how to manage and control privacy. Privacy, however, goes beyond how to protect financial information or individual passwords to include how to manage personal disclosures. Applying the theoretical

framework of Communication Privacy Management to current and emerging technology provides insight into communication behaviors of its users as they balance privacy issues against their daily communicative needs. No matter the means of communication, receivers make choices on what to disclose and what will remain private when communicating with others. Decision criteria aid in the development and employment of underlying privacy rules (Petronio, 2002; Petronio & Durham, 2008). A better understanding of the criteria used to make privacy decisions when using emerging communication technology and social networking sites will enable researchers to better predict communication behaviors.

Decision criteria are affected by a number of factors, including cultural and individual differences. Like many areas of communication studies, comparisons across cultures are relatively rare (for an exception, see Worthington et al., 2012). Such studies would allow for the identification of commonalities as well as cultural differences in how individuals manage privacy, assess co-ownership, and develop privacy rules. Along with studies exploring cultural differences, research into individual differences is needed. How might differences in self-consciousness, interaction-involvement, communication apprehension, compulsive communication, and related psycho-social constructs impact privacy management decisions and rule development?

While a number of studies have focused on Facebook users (e.g., De Wolf, Willaert & Pierson, 2014; Waters & Ackerman, 2011), few have addressed CPM by users of other sites (e.g., LinkedIn, MySpace, Meetup, VK, etc.). Such studies may provide a better understanding of underlying factors associated with boundary permeability and turbulence, particularly as related to areas such as the effect of privacy breakdowns on social relationships, self-disclosure, and privacy management practice.

Finally, the intersection of communicative affordance and CPM provide another potential area

of study. An affordance describes the “mutuality of actor intentions and technology capabilities that provide the potential for a particular action” (Majchrzak, Faraj, Kane, & Azad, 2013, p. 39). Schrock (2015) argues that communication has been inherent in many explanations of social affordances, particularly those that highlight the role of perceptual cues on individual perception and social networks. This approach to affordance goes beyond design features (e.g., apps, screens, etc.) to include the impact of a technology on human communication processes, such as communication privacy management. How might perceptions of technology and communication affordance be informed by user concerns of personal privacy?

CONCLUSION

Emerging communication technologies and social networking sites have significantly impacted how individuals and groups communicate with one another. However, while the methods of communication have changed and while they certainly can affect communication processes, at their center are people communicating with other people. Communication Privacy Management theory represents one of many human communication theories that may provide insight into how individuals use technology to communicate with one another. Through its application, researchers may ultimately find that while the means of communication change, individual privacy concerns remain the same.

KEY TERMS AND DEFINITIONS

Boundary Permeability: The level of access, scope, and extent of private information an individual is willing to share with others.

Boundary Turbulence: Occurs when privacy expectations of the original owner of information are not met and a confidentiality breach occurs.

Communication Privacy Management Theory: A theory addressing the tension people experience when choosing what personal information to reveal and what will remain private when interacting with others.

Confidants: Individuals who are given access to private information.

Confidentiality Breaches: Occur when privacy expectations of the original owner of information are not met by co-owners of information.

Deliberate Confidants: Individuals who are purposely given private information and readily take on obligations and responsibility associated with co-owning the information.

Information Co-Ownership: Occurs when access to private information is granted to others, who then take on the trust and responsibility that comes with co-ownership of previously private information.

Privacy Boundaries: Personal boundaries separating public and private information. They govern who has control of and access to personal information.

Private Information Ownership: The belief that individuals own their personal information and have the ability and right to share or protect that information from others.

Reluctant Confidants: Individuals who receive unwanted private information and may experience unwanted feelings of obligation and responsibility.

The Dual Nature of Participatory Web and How Misinformation Seemingly Travels

S

Sameer Kumar

University of Malaya, Malaysia

INTRODUCTION

Social media is called ‘social’ as it is primarily ‘produced’ by people (user-generated) and there is less or no commercial aspect involved. The platform lets people to communicate in horizontal using multimedia (text, photos, videos, music, etc.), thus, also making them reporters and publishers in the process. Social media has brought in a revolution in the way people express their views and share their likes and dislikes (Asur, Huberman, Szabo, & Wang, 2011; Ellison, 2007; Kumar & Jan, 2011, 2012). This media sits on Web 2.0 technology. In this article the author argues that the web is a neutral medium which could be used from transmitting good and bad information. A hypothetical model of how misinformation travels is also presented.

BACKGROUND

Web 2.0 does not refer to the update in the technical specification, but rather new applications and technology that makes web experience more interactive. While talking of Web 2.0 the applications such as Ajax or Openlaszlo are stated, which make the web as a ‘Participatory Web’. This is in contrast to the earlier version Web 1.0 which was essentially an ‘Information Web’. The main features of Web 2.0 are user-interaction, dynamic content, meta data and scalability (Best, 2006). Social media sites such as Facebook and Flickr make use of Web 2.0 technology in order to give interactivity to their sites. McAfee (2006) refers to the following technological features of Web

2.0, acronymed as SLATES – Search, Links, Authoring, Tags, Extension, Signals. Search enables keyword search, Links helps in linking to other documents within the page or elsewhere on the Net, Authoring refers to the ability to update, iterate and cumulate content, Tags help in searching and helping to avoid category rigidity, Extensions help in leveraging the Web as both document server and application platform, and finally, Signals that help to inform users of changes in the social media content. In more technical terms, Web 2.0 technology is based on two sides – Web browser side (client) and Web server side (server), and they utilize softwares like Ajax, JavaScript, Flash etc. to fetch data to and from the Web server and to carry on instant updates. Flash software technology is also used in music and video sites. YouTube is a good example of Flash technology. The popularity of Web 2.0 has encouraged all web allocations with collaborative and interactive functionality to append the term 2.0 to it – interestingly these name are, for example, Library 2.0, Publishing 2.0, Social Work 2.0, Travel 2.0, and the list goes on. Essentially all these Web applications use Web 2.0 technologies to provide better functionality in their domain of business.

In this article that author argues that although these new technologies are making Web even more popular and accessible, they are also making people spend long hours on seemingly unimportant and irrelevant conversations, dialogues, reviews and opinions. According to Andrew Keen, writer of ‘*Cult of the Amateur*’, Web 2.0 has “created a cult of digital narcissism and amateurism, which undermines the notion of expertise” (“Web 2.0 has created a cult of digital narcissism and

DOI: 10.4018/978-1-5225-2255-3.ch606

amateurism?," 2010). Just as a river, that carries everything – good or bad – as it flows, social media makes no discrimination between what it carries. Some people use it for a good cause, some as a campaign tool, while others use it to spread hatred and false news.

Through surveys and content analysis of some comments of Social Media, which includes blogs, discussion forums, newscasts, market research studies and traditional websites, on three determinants – 1) social service, 2) politics and 3) misinformation – we do a critical examination to see if social media is a double-edged sword – a technology which could be used to transmit both good and bad information.

A Great Vehicle for Political Propaganda

In politics, people elect their representatives. These representatives then govern a county or a country. Political news have always captured the front pages of our newspapers. A country is more secured and safe if its political climate is stable. The way people elect their representatives and the way representatives campaign during the elections, differ from place to place and from country to country. Let us take the example of two biggest democracies in the world – India and USA. In India, a large percentage of people who cast their votes are still farmers, low income group people and the elderly. Political parties in India, thus, go all out in wooing the farmers and it's the farmers who actually bring a candidate to power. Unfortunately, most of the farmers are either illiterate or semi-literate who have almost nothing to do with Computers or latest online technologies. One can forget about how Social media would ever affect their voting decisions. In contrast, USA is a country where most of the voters are literate and have access to internet and other latest electronic gadgetries. The way social networking is bringing people together, its communicating power and speed, its "peer to peer" and "word of mouth" potency have been understood

quite well and quite early in the game of politics in America.

Social media based videos in particular are becoming a popular medium for political propaganda (Noguera & Corretero, 2010). This was clearly evident in the last major US presidential elections (year 2008) which remained in the news for over 2 years – first the elections between Hillary Clinton and Barack Obama within the party and then the fight to the finish between the Democrats and the Republicans. Both McCain and Obama used Social media technologies to the hilt. We particularly know Obama for his Social media savoir-faire. Barack Obama appointed Scott Goodstein as External Online director ("How Obama used social networking tools to win," 2009) for *Obama for America*. According to Scott, there were three main factors instrumental in the effectiveness of the campaign – 1) using deadlines to test new ideas, 2) allowing consumers to engage and, 3) validate and moving with the marketplace. There's lot happening on the Net which one can either ignore or engage in it. Scott believed that they were able to successfully engage and move with the marketplace, which helped them win the elections. His social media strategies helped attract 1.7 million supporters on Twitter, 6.5 million on Facebook and over 2 million supporters on MySpace. Speaking in Singapore, he stated that Social Media put Obama's slogan 'Change you can believe in', front and centre. Obama, himself an exceptional communicator, needed the right messenger and social media proved to be just that right one. It helped Barack Obama's message to clearly reach the audience. People were talking and discussing about him in Facebook, MySpace, Twitter and everywhere.

US has been seeing a shift in media consumption. There are lesser and lesser number of people interested in TV or newspaper. More and more people have been reaching out to Internet for news and entertainment. Understanding this, the online campaign team of Obama meticulously handled social networking campaign platforms, including those that were catering to the ethnic

communities. Obama's willingness to experiment with new communication tools gave the initial fillip. In the present times, the competitiveness in elections is intense and just 5% votes shift can make a candidate lose or win elections. Propaganda through social media coupled with good support from ethnic groups - such as Indian-americans, Afro-americans, etc, probably gave Obama the vital vote shift.

However, if Social Media could give positive results, it could also do the opposite. This is what happened with Sarah Palin and McCain lost the US presidential elections.

One of the bloggers ("The Perils of Modern Communication," 2009) comments and writes about what he read in WaPro:

The difference is that now the masses are technologically enabled, amplified by a twillion tweets. Everybody's got a megaphone, bless democracy's heart.

But when a protest of one (or a few) can instantly morph into a babble of thousands, rabble-rousing becomes a hobby -- and rational debate becomes an oxymoron.

The comment speaks about how a protest can amplify manifold.

In the case of Barack Obama one saw how Twitter updates, Facebook and Myspace communities helped him gather funds, volunteers and publicity. A dedicated social networking site mybarackobama.com, powered by 'six apart' company, was extensively used. However, after the campaign was over, his twitter stream went silent for weeks and there was little to no engagement directly by the Obama camp on other sites as well. Probably, politicians have not yet realized that it is not just enough to make social media as a campaign tool but also to use as an effective tool to connect to its faithful voters post-election results. It may also be true that political parties are scared that the power of social media would soon make them unpopular, if unpopular policies

are enacted (i.e increase in taxes), and hence are not comfortable at engaging with people post elections, as yet.

We, thus, are seeing that successful experiment with Social Media in politics has now made politicians and political parties to stand up and take notice. It also reminds them that it is not just sufficient to win elections but live up to their manifesto. Because the users of Social Media are no bovines – they will write, share and speak-up about any topic or issue. If they do not perform while in power, the same people who voted for them would bring them down, when they stand up for the next term. For political parties and politicians, writings and feedback on social media are a nice way to gauge what people are thinking about them.

A Platform for Social Service

In day-to-day context, the word 'social service' often means 'caring for humanity'. When we hear that certain organization is doing social service, we understand that they are providing humanitarian service. So how can this Social media work for social service or cause? Can it help in social entrepreneurship?

Late C.K. Prahalad, the management Guru, said that it is important to target the BoP (Bottom of Pyramid), in order to eradicate poverty (Prahalad, 2010). Half of the people in the world are living under \$2.5 a day. As commercial companies are more and more targeting people who have money, there is a widening gap between the have and have-nots. This gap could be targeted by social entrepreneurs. It is a huge untapped market that could be harnessed both for profit and eradication of poverty. Melting of borders has also made social entrepreneurs bring their innovations to different parts of the world. The success of Grameen Bank's micro-credit model, for example, is now being implemented in other parts of Asia, Africa and even Europe, with varying degree of success.

Social entrepreneurs in the west are leveraging the power of social media to reach out to the devel-

oping world. Yonus's Grameen bank in Bangladesh is one of the earliest successful examples of social entrepreneurship. Grameen bank's unique lending model went on to prove that people would pay back their loans even when they are given without co-laterals. Grameen bank had a 99% loan return rate which is much higher than commercial banks. The same micro-finance concept is taken up of kiva.com that works as a connector between the people willing to lend money to people in need. People who need money are first verified by the regional field partners and once verified, their profile is posted on the kiva website. By remitting as low as 25\$, one can contribute to one or multiple loan-requesters. People who lend money are satisfied that it is going for the right cause. Once the borrower starts repaying, the money is repatriated to the lenders in a phased manner,. Field partners keep the interest to defray their expenses. The default rate is near zero and the success is huge, so much so, that kiva.com as of 2013 had helped people with about half a billion US\$ of loans. A loan request is fulfilled in just 15 hours, on an average.

The question remains whether globalization has created a new breed to social entrepreneurs with fire in their belly to do something transformational and bring about a social improvement. The internet has brought the awareness of social entrepreneurship. For example, many people have come to know about this kind of entrepreneurship by visiting the asoka.org or kiva.com websites.

Improvement in the level of education is another area where social entrepreneurs have been working on. Negroponte's one-laptop-per-child (<http://laptop.org/en/>) is a wonderful example of this. One laptop per child is MIT's project that has developed a laptop for school children and it costs under US\$200. The project has plans to bring it down to US\$100 eventually. It is a major project that it being implemented in association with the governments of both the developing and the developed worlds. India too is working to come out with an ultra-cheap laptop for school children that some say would well cost below US\$ 100. It

is important here to know that these projects help students to have access to latest digital technologies. Better access to information over social media and learning material undoubtedly improves their knowledge level and grasping power. It the Social media that spreads the word of mouth. You one has something worthwhile to sell or give and if people like it, it will spread like wildfire over the internet. One-laptop-per-child would not have become known across the world had it not been discussed in blogs and other niche networking sites. It is important to understand that Social Media is not only about sites like Facebook and Youtube. It is also about such sites like Kiva.com that are able to provide direct help thousands and thousands of needy individuals.

One of the bloggers ("The Humanitarian Power of Social Media," 2009) a recent impact of social media in motivating people to donate blood. The bloggers decided to donate blood in Austin, Texas, and they had just three days to spread the message. To promote the event, the bloggers used blogs and asked other bloggers to write about the event. The result was satisfying – over 100 people turned up to donate blood at a centre that gets on an average 40 people donating blood on a given day. Among the donors were people who were donating blood for the first time. In another example ("Capital Area Food Bank of Texas," 2009) of how social media could benefit humanity – a company TysonFoods decided to donate 100 pounds of food (limited to a maximum of 35,000 pounds) for every comment they receive on the website. This message was twitted across (through microblogging site Twitter.com) and within 6 hours the limit was reached. The company got over 350 comments and the donation of 35,000 pound of food was made to Capital Area Food Bank of Texas's HAM-up event. Social media tools like weblogs, social networks and video chats are used in both large and small hospitals which are 'reengineering' the way patients and doctors interact (Hawn, 2009)

The consumer to consumer communications have been greatly expedited due to the viral nature of social media (Mangold & Faulds, 2009). This

can send good message very fast. If one have a blood camp in his neighborhood or there is sudden need to help someone in dire need information could be circulated through Facebook. Twitter, the micro blogging network, is making this even faster. Just one twit and all followers of the individual on Twitter are immediately informed.

But Also a Vehicle for Misinformation

Social Media is a popular opinion sharing platform. It is to everybody's benefit if these opinions and views are constructive. Such an endeavour, for example, can help a child in need of blood of a rare blood group. However, what happens if the same platform is used for spreading hate or some other kind of misinformation? Social Media is only a medium - it carries everything and carries it fast. So if someone wants to spread rumour about a UFO or Michael Jackson rising from the dead, just posting a grainy video footage on Youtube can make the rumour spread like wildfire. It will be carried forward in other blogs, copied, Digged, Reddited, Stumbled upon and Twitted in no time. Harmful rumors spread and cause people to panic (Hashimoto, Kuboyama, Shirota, & Ieee, 2011) To prove this point, RTL carried out an experiment to show how fast rumours could travel on the social media. They posted a fake video of Michael Jackson (now no more alive) on Youtube. Within a matter of just one day it was viewed over 7,00,000 times and many believed that the video was true. The video was removed from YouTube the next day.

SOLUTIONS AND RECOMMENDATIONS

In social Media, a person is credible if he has a popular blog or if he active in the forums. For example, Sarah Palin, the vice presidential candidate of the US 2008 elections, was the governor of Alaska, enjoying over 93% popularity, when she was chosen by McCain, in the run-up to the

US Presidential elections. However, in the social media there was grapevine that Sarah Palin's daughter Bristol was infact the mother of her (Palin's) last child ("Governor Palin Babygate Debunked!," 2008). The source that spread this news went blow-by-blow giving reasons and proof of why this was true. Palin camp did not take the initiative to clear the clouds till the time it became a very hot topic in the formal and informal media. Infact, the formal media (newspaper and TV) took cues from what was circulating in social media and made the topic hotter. McCain Camp tried to douse the fire by doing some unusual things like even carrying out *Adwords* advertisement and driving that traffic to their election website. Palin did come up later to tell that her teen-aged daughter was pregnant with her boyfriend Levi Johnston ("Bristol Palin," 2009). However, the damage was so huge that, some say that this issue was one of the contributors to McCain's loss in the elections. Furthermore, once immensely popular Sarah had her popularity hugely diminished. In 2009, she resigned as the Governor of Alaska. Fig. 1 shows a way rumour through video seemingly spreads.

Misinformation is part of Social Media. Not only for popular persons, it could also happen to products or companies. There have been several cases, especially small companies, who have suffered heavily in the hands of this social media con-artists. Those who only have internet business are always at a risk to suffer the maximum damage if false information gets around. They are picked up by search engines, which keep it indexed for ever (blog posts never die). Someone determined to cause brand damage to a company or product could set-up blogs, join forum and post false information. Depending how influential the blogger is, he could make a serious dent in the popularity of the product or company. So the question again arises, how to do the damage control? Here I present a few steps, in Figure 2 that could be taken when misinformation is being spread and the individual/company is made aware of it.

Microblogging with Twitter is increasing the speed of information and misinformation dissemi-

Figure 1. How a rumor or misinformation seemingly travels through video in YouTube

Figure 2. Possible steps to control misinformation damage on social media

nation over the social Media. 80% of Twitter's 140 characters-or-less messages are delivered through the mobile phones or PDA. Suppose some popular Twitter user has 30,000 followers, in one instant he could influence that many followers. Additionally, followers of this popular person may have their own following. If the information is worth transmitting these followers twit to their followers, creating a dizzy chain effect. Millions of people are made aware of information – false or true, in just

a few hours or may be a few minutes. One of the bloggers ("Social media diseases," 2009) writes:

24. Art Says:
August 12th, 2009 at 1:58 pm
@IVAN3MAN:

"FALSE beliefs are everywhere. Eighteen percent of Americans think the Sun revolves around the Earth, one poll has found. Thus it

seems slightly less egregious that, according to another poll, 10 percent of us think that Senator Barack Obama, a Christian, is instead a Muslim. The Obama campaign has created a Web-site to dispel misinformation. But this effort may be more difficult than it seems, thanks to the quirky way in which our brains store memories — and mislead us along the way.”

Who did they survey and why am I not surprised?

In Twitter such misinformation is becoming common. The originator of this misinformation may be doing it for fun or may himself think it is true. However, once it goes few layers down, the information is modified, changed and believed even more. After traveling a few layers, the ‘node’ does not know where it originated from and thus, either believes or disbelieves it.

Information over a network travels fast and when the network is made of people who give credibility to the word of mouth, it travels even faster. It is pertinent to note that misinformation, rumors and negative news travels even faster. As the old adage goes “if you bite a dog it is news”. Because of the nature of humans to give importance to negative news, there is lot of false news circulating and being believed by the people.

Satirical sites such as Onion.com do not deliberately circulate misinformation (visitors know that these news are meant to entertain) hence must not be confused with sites, news or videos that pose themselves as true but in reality may be just hoaxes. One of the possible ways to reduce the harmful repercussions of incorrect and malicious information is to be informed if the information being transmitted is really true nor not. Those news that unbelievable are in the first category to be checked for its truthfulness. There are several sites that debunk misinformation, rumors, myths, etc – snopes.com (Mikkelsen, 2016), being among the most popular. With the US election season (2015-16) now in US, lot of political misinformation is floating around. To get to the bottom of truth, political fact checking could be done by visiting the sites like, politifact.com.

FUTURE RESEARCH DIRECTIONS

Although spread of misinformation is a topic that needs immediate scientific scrutiny, the research in this area has been laggard so far. In the wake of the recent Paris attacks (NBCNews, 2016) at a deluge of misinformation that also flooded the social media, there is an urgent need to conduct studies on how false and fabricated information. A hypothetical model is presented in the article. The spread of misinformation of which social media is the primary carrier nowadays, needs to be understood and checked so that people are aware that not everything that they see or hear on social media would be true. Scientific community too is under its grips where only certain portions of a scientific study for example is used to influence the idea. ‘Echo chambers’ bring about confirmation bias leading to misinformation such as conspiracy theories (Feldman, Myers, Hmielowski, & Leiserowitz, 2014; Harvey, 2016). Hence the future research could look into other models of how misinformation travels and the ways of limiting the spread of fabricated information of social media. Social network theory, for example, is a powerful way to understanding these mechanisms where a “influence limitation” could aid in restraining ‘bad’ information with ‘good’ information (Budak, Agrawal, & El Abbadi, 2011).

CONCLUSION

Unlike traditional media which has an editorial board to oversee what is published and what is not, social media is free for all – there are no editors and one could publish whatever he or she wanted. In Social Media there is no formal filter. The person receiving it has to use his/her judgment to separate misinformation from true information.

Here an attempt was made to understand the impact of Social media on Society. Social media is rapidly evolving, hence it is impossible to gauge its real impact. We learn that politicians in developed countries, like US, are using Social Media

for the purpose of election campaign. However, there is lack of engagement with voters after the campaign. SM is being used for Social Entrepreneurship, esp. Micro-financing. Volatile and viral nature of SM is carrying both information and misinformation at extremely fast pace. It may be rightly concluded that Social media is a medium, which could be a double-edged sword, capable of both good and harm.

KEY TERMS AND DEFINITIONS

BoP: In an acronym of ‘Bottom of Pyramid’ that refers to the poorest, yet largest strata of people. The poorest are usually defined by those group of people having earning of under USD 2.5/day.

Echo Chambers: the area of the virtual media where ideas and beliefs are reinforced through repetitive broadcast.

Influence Limitation: A process where misinformation (or ‘bad’) is diluted or replaced with correct (‘good’) information. Such an endeavor potentially reduces the harmful repercussions of misinformation.

Misinformation: False information, rumors, etc. circulating through the online social media.

Social Media Sites: Websites like Facebook, YouTube, Twitter, Instagram, etc, where people access the Internet to interact (chat, share photos and videos, communicate, etc.) with other people online.

Social Network Theory (SNT): SNT theory looks at associations in terms of ties and nodes, where nodes form a tie if there is some kind of relationship between them.

Web 2.0: Often referred to as the second version of World Wide Web (or simply ‘Web’) that has interactivity. The earlier version of Web had static pages with little or no interactivity.

Effective Cultural Communication via Information and Communication Technologies and Social Media Use

Androniki Kavoura

Technological Educational Institute of Athens, Greece

Stella Sylaiou

Aristotle University of Thessaloniki, Greece

INTRODUCTION

Cultural organizations need to adopt contemporary methods and ways of communication for heritage management. Raising people's interest for cultural heritage may take place via the implementation of innovative communication tools that allow for engagement to take place. Research though has shown that cultural organizations are more reluctant than firms are to implement a two-way communication process with new technologies and social media. Do cultural organizations employ Information and Communication Technologies (ICTs) and social media in an interactive approach? This chapter aims to illustrate the significance that should be attributed to innovation through the use of technology for communication purposes by cultural organizations. The way communication trends take place in the field of cultural management and communication is presented, along with an overview of the technological outlook that can be invaluable. The use of innovative communication tools that are employed by cultural organizations for their communication strategies has been little researched as a topic. This study aims to add to the literature on the use of social media, mobile devices and ICTs by cultural organizations.

Technological advances have enabled a dynamic and effective communication of cultural organizations with their audiences and made more attractive. ICTs are used to enrich, transform and enhance the cultural experience. They can become

a powerful communication channel that may be a virtual 'direct' experience. They can disrupt linear sequences and provide usable and accessible in technology, content, navigation solutions for all people, irrespective of their age or abilities. Furthermore, the ICTs may permit exploration of cultural information, learning-by-doing in game-like environments that foster creativity and innovation.

The motivation for this chapter was the examination of the reasons why cultural organizations should use ICTs and social media in the cultural communication process with their public. The aim of this chapter to present the most popular communicative media that can be used by cultural managers to promote their cultural activities and organizations. The implementation of innovative and emerging technologies by cultural organizations has a role to play at their management and communication level of the organization. The chapter describes new applications employed by cultural managers that take into account the needs, preferences and expectations of the public and encourage them to interact with the cultural content and context. This may allow a more holistic approach to take place in regard to the trends and future outlook on the adoption of ICTs.

The adoption and implementation of innovative communication technologies may bring the visitor closer and connect him/her with the cultural organization. Curators and professionals who are in charge of media communication strategies in

cultural organizations may also find this study useful, because it illustrates innovative ways to incorporate web technologies in the promotion of the organizations and in the identification of visitors' needs and preferences.

However, the cultural messages shall use the appropriate medium and communication models to be transmitted via contemporary communication models. The use of innovative communication tools that are employed by cultural organizations for their communication strategies has been little researched as a topic (Padilla-Melendez & del Aguilla-Obra, 2013) where geographical and temporal boundaries are minimized (Bilton, 2015; Jeffres, 2015) and the co-creation of information via social media allows people to create content and post information online to like minded people.

BACKGROUND OF RESEARCH: CULTURAL ORGANIZATIONS, CULTURAL MARKETING, AND ICTS

This chapter presents (a) both the implementation of innovative communication technologies with the use of ICTs via computers, mobile phones, telephone lines to access and manage electronic data on the web from the cultural organizations' point of view in order to illustrate the possibilities on offer for managing and promoting their services and (b) the implementation of social media that are internet-based innovative communication tools that bring people together through the use of user-generated cultural content. In doing so, a two way communication and engagement between cultural organizations, art and audiences can be promoted and cultural managers may more fully adopt both ICTs and social media.

There is a tendency of cultural organizations to overall ignore competition as part of the marketing approach; when they do so, they attend those cultural organizations that they are in their immediate whereabouts (Bennett, 2015). Cultural organizations need to embrace new strategies of marketing and use marketing tools and techniques,

as well as of social media, to disseminate their content and promote their activities to reach and communicate with new audiences (Fletcher & Lee, 2012), to increase their visitors and build stronger relationships and loyalty.

Cultural organizations are interested in developing relationships with different categories of the wide public. Firstly, simple promotional techniques were enough to achieve their goals. Nowadays, due to the economic crisis they needed to adopt a more sophisticated approach to marketing (Kolb, 2013). Furthermore, the explosion of ICTs and the extensive use of social media by cultural organizations suggested a 'transformation in cultural communication' (Russo, 2011) and an adaptation to users' changing usage behavior and expectations related to technological development and cultural changes (Shyam Sundar, Go, Hyang-Sook, & Zhang, 2015). Furthermore, they provided opportunities for user-generated content and co-creation (Holdgaard, & Klasturp, 2014; Sylaiou, Basiouka, Patias, & Stylianidis, 2013), education, enjoyment and entertainment (Charitonos, 2011; Hou, Wu, Lin, Sung, Lin, & Chang, 2014; Katz & Halpern, 2015; Kellner & Kim, 2010; Russo, Watkins, & Groundwater-Smith, 2009; Selwyn, 2009; Vavoula, Sharples, Rudman, Meek, & Lonsdale, 2009), and social utility for online communities (Allen-Greil & MacArthur, 2010).

In a continuously changing environment social media are a major challenge for cultural organizations, since they change the ways cultural meaning is perceived and the cultural products are consumed. They have become a part of everyday life and it is expected that cultural organizations adopt them to communicate with the wide public. Their use and growth have led to significant changes in cultural communication and the marketing strategies need to get updated and become adjusted to the new conditions. Social media can make cultural organizations' aims and scope attractive to a broader audience and include not traditional audiences and provoke their visit not only to their digital extension, but also to the physical site. Furthermore, they permit the interaction with the

wide public and they may collect valuable information about their preferences and opinions. They create new and novel ways for communicating, understanding and experiencing culture. Social media promote innovation, the creation of online communities and participatory culture.

The economic crisis and the budget cuts and the reduction of the state grants changed dramatically the cultural landscape and have led cultural organizations to a shrinkage in their activities, or even to closure. Technological advances have emerged as areas of crucial interest, since they are making it possible to use sophisticated tools to provide solutions to problems created by economic crisis. ICTs may have a multi-faceted contribution to the relationship between culture and the public and can play a decisive role in making cultural content and context available, in enhancing experience through meaningful and constructive interaction between culture and the public.

HOW ARE ICTs AND SOCIAL MEDIA EMPLOYED WITHIN THE CULTURAL COMMUNICATION PROCESS

ICTs and social media are slowly implemented by cultural organizations in order to connect with their public and engage with the users informing them about the activities organized by cultural professionals and interacting with them in a reciprocal relation that allows the co-creation and exchange of experiences. The next sections present innovative ways with which ICTs and social media are implemented by cultural organizations and thus, how they can be further employed by cultural organizations.

Innovative and Emerging Technologies and Challenges of Cultural Organizations

There is an ongoing research that has taken place in regard to the potential of ICTs implementation

to cultural organizations (Gonzalez, 2015; Kéfi, & Pallud, 2011; Royston & Delafond, 2015; Scoffield & Liu, 2014; Sylaiou, Economou, Karoulis, & White, 2008; Sylaiou, Liarokapis, Kotsakis, & Patias, 2009). ICTs have made the content and context of museum collections more accessible and attractive to the wide public and have enriched the museum experience.

The implementation of innovative technologies by cultural organizations allows for the provision of customers with improved services since visitors may have a holistic approach in regard to the exhibits of the organization and be able to interact with them. In addition, the public can be informed at any time about the events and procedures of the organization with the latest technologies and the way cultural heritage is approached and managed. Furthermore, emerging technologies allow for the collection of data as far as cultural preservation and cultural management is concerned of rare collections and archives that may become available to the public with the adoption of new technologies. The following section presents the different purposes of use of emerging technologies and ICTs.

According to Bakhshi & Throsby (2012) have identified four categories of ICT innovation in cultural organizations:

- Innovation in audience reach in terms of engagement with audiences.
- Innovation in artform development in terms of encouragement of new and experimental work and incorporation in their programming.
- Innovation in value creation in terms of new ways to measure the economic and cultural value and to translate these into terms that policymakers, funding agencies, donors and private investors can relate to.
- Innovation in business management and governance in terms of organizations' business models review and of a search for innovative financing strategies.

Web 2.0, the second generation of the Web, or the ‘participative Web’ has revolutionized the way of interaction and participation of the users. Web 2.0 technologies support and advance the information and knowledge dissemination in a social way. More specifically, crowdsourcing technologies make use of the “wisdom of the crowd” and aim at integrating many different audiences, raising public awareness, encourage active participation in the preservation and presentation of cultural heritage, which leads to the creation of a participatory culture and the democratization of knowledge (Sylaiou, Basiouka, Patias, & Stylianidis, 2013).

Interaction of multiple channels from the social media networks can be combined complementarily with real life events that the cultural organization manages that aim to engage with the user in an interactive and expressive way and not with the traditional one way of communication (Lazzeretti, Sartori, & Innocenti, 2015). Social media’s proliferation and extensive use have transformed the cultural experience and provide many opportunities for learning, active participation and creativity. However, the main contribution of ICT is to involve communities and promote public dialogue and collaborative frameworks, create the sense of community and provide more transparency. They have sought to become the vehicle for fulfilling the public’s expectations and change in the relationship between cultural organizations and the public.

ICTs may have a multi-faceted contribution to the relation between cultural organizations and the wide public. More specifically, Internet technologies have the tremendous potential of offering virtual visitors ubiquitous access via the WWW. The Internet combined with:

- Virtual Reality (VR), a simulation of a real or imaginary environment generated in 3D by digital technologies that is experienced visually and provides the illusion of reality.
- Augmented Reality (AR) is considered as an extension of VR. AR tools present a view of the real-world environment whose

elements are augmented in real time by computer-generated sensory input, such as video, graphics, GPS data or sound (Promoter, 2015).

- Augmented reality and holograms systems that ‘augment’ reality with holographic displays (Mavridis & Hanson, 2009, Kim & Wohn, 2014).

Geographic Information Systems (GIS) that store, manage, analyze, visualize and present all types of spatial and geographical data have already transformed the cultural experience through their ability to document, organize, visualize, preserve and disseminate a plethora of types and vast amounts of cultural data. As a result, ICT have been extensively used by cultural organizations and have evolved into a discrete hybrid disciplinary field with its own especially dedicated conferences, such as the Computer Applications and Quantitative Methods in Archaeology (CAA), the Virtual Systems and Multimedia Society (VSMM) and the Virtual Reality, Archaeology and Cultural Heritage (VAST), Digital Strategies for Heritage (DISH) conference, ‘Art and Interaction’ as integral part of the Special Interest Group on Computer–Human Interaction (SIGCHI) Creativity and Cognition series, Digital Arts in Association for Computing Machinery’s Special Interest Group on Computer Graphics and Interactive Techniques (ACM SIGGraph), the Conference on Transdisciplinary Imaging at the Intersections of Art, Science and Culture and many more.

Nowadays, emerging ICTs help cultural organizations to face challenges concerning connections between heterogeneous data from different sources and enhance visitor experience. Some of these emerging technologies are mentioned below:

- Linked Open Data (LOD) linking content among cultural heritage collections and between those collections and collections created for other purposes by Libraries, Archives, and Museums (LAM) (Oard, Levi, Punzalan, & Warren, 2014).

- Internet of Things (IOT), a network environment of things, or everyday physical objects with unique identifiers will be connected to the Internet, able to identify each other as devices and interact in an intelligent way with each other. Its application to arts and culture (Senior, Moreton, & Dovey, 2015) and its interaction with wearable and mobile devices, contents retrieval from the Cloud and services in culture provision to internal and external users (Mighali et al., 2015) are still under exploration. Emerging Radio Frequency Identification Detection (RFID) technologies will connect things between them, objects, places, people, will apply in cultural spaces to help users to get the correct information which is better than traditional guides (Karimi, Nanopoulos, & Schmidt-Thieme, 2012; Sen, Roy, & Sarkar, 2014).
- Mobile apps that can be used for:
 - Learning in the framework of formal (Maher 2015) and informal learning (Katz & Halpern, 2015).
 - Cultural experiences enhanced with Augmented Reality (Damala, Marchal, & Houlier, 2007; De Angeli & O' Neil, 2015).
 - Digital storytelling (Negrini & Di Blas, 2015; Hart & Brownbill, 2015).
 - User-generated content and co-creation (Mason, 2012).

The next section presents the implementation of social media from cultural organizations in their communication activities.

The Implementation of Social Media From Cultural Organizations

This section presents the most important social media that can be employed by cultural organizations in their communication activities. Various online applications facilitate the “sharing of information, experiences, and perspectives throughout

community-oriented websites” (Weinberg, 2009, p. 1). Social media consist of “a group of Internet-based applications that build on the ideological and technological foundations of Web 2.0, and that allow the creation and exchange of User Generated Content” (Kaplan & Heinlein, 2010, p. 61) that help cultural organizations to reach new audiences, increase participants’ engagement and the likelihood of a visit (Theocharidis, Nerantzaki, Vrana, & Paschaloudis, 2014).

Among the most commonly used social networks user-driven channels that are employed by cultural organizations, such as museums, are Facebook, Twitter, Blogs, TripAdvisor, Flickr and YouTube.

- **Facebook:** Facebook can be used as a Public Relations’ tool for promotional and communicational purposes (Kelly, 2014; Kotzaivazoglou, Paschaloudis, Sylaiou, Nerantzaki, & Mantzirtzi, 2016; Proctor, 2010; Russo, 2011, 2012; Trembach, & Deng, 2015). It also may be used to promote a cultural organization’s events and announce important but it may also receive participants’ feedback to get their comments regarding their experience allowing the cultural organization to improve its services based on visitors’ comments made. The real case is that cultural organizations do not usually see Facebook as an interactive environment limiting its potential (Lazzeretti et al., 2015).

The social networking site of Facebook can be implemented to create an interactive communication with the target group of the cultural organizations.

- **Twitter:** Micro-blog is a type of blog that lets users publish short text updates while the act of using these services is called micro-blogging. For example, Twitter is a free micro-blogging service where users publish short messages which contain 140

characters or less, the so called tweets on the Twitter website or they may use their mobile phones to send sms text-messages in real time to their connected environment of this network based on the retweets that will take place and based on how big the social network is (Bastos, Galdini Raimundo, & Travitzki, 2013). In that way, information sharing may be accomplished online and many people even if they have never met may participate.

- **Blogs:** Blogs are websites that contain comments, forums for conversations, news and quite often hyperlinks provided by the cultural organizations. They create a friendly space for discussions, they connect people with organizations; blogs provide a valuable engagement tool for interacting the public and forming communities. They can also be considered as educational content platforms. Blogs offer cultural organizations a valuable way to reach a wider audience through search engine optimization and through the blog's inclusion in Google search (Bomboy & Sherman, 2014).
- **TripAdvisor:** TripAdvisor allows for the collection of user generated content in regard to a cultural organization located in a specific area. Available reviews are there for the potential visitor to see and comment on. The possibility of geographically collecting information about the cultural organizations of the region and user generated content under reputation management facilities (Ntalianis, Kavoura, Tomaras, & Drivas, 2015), allow the cultural manager to have feedback for his/her organization. Information that is created by other users about a cultural organization and provides good material and recommendations about it while at the same time, it is free advertisement for the organization.
- **Flickr:** Flickr is a photo sharing site. As such, it is very much associated with photographs taken when on holidays where

cultural tourism and visiting of cultural organizations may be the case. In fact, it has been found that visitors pay attention to Flickr advertisements but also employ it as a communication tool to upload the photos taken from their trips (Kavoura & Stavrianeas, 2015).

User generated content is created on Flickr and Dotan & Zaphiris (2010) found the existence of patterns on language and tagging in regard to specific countries and uploads on Flickr. Lazzeretti et al. (2015) on the other hand, found that the use of Flickr from cultural organizations had little success as a two way communication since there was a lack of interest by users. The use of a specific language in this communication's technological tool may attract visitors and users of cultural organizations that may gather on Flickr based on specific tags that are of interest to them and thus, make it more attractive.

- **YouTube:** YouTube, another technological instrument can be used to broadcast interviews with curators as suggested by Lazzeretti et al. (2015).

Significant exhibits in the room of a museum or the organization of a cultural festival at a well equipped venue, for example, can be briefly presented on You Tube employing narration, sound and image and thus, creating a rich media result.

RECOMMENDATIONS AND FUTURE RESEARCH DIRECTIONS

The implementation of innovative communication tools by cultural managers allows for engagement to take place between the cultural organization and the users. The use of technology for management and communication purposes by cultural organizations allows for a two way communication with their audiences that may bring the visitor closer and connect him/her with the cultural organization.

Cultural managers may use the above mentioned innovative communication technologies presented in this chapter in order to manage and communicate their organizations and services. There is a long way before all cultural organizations adopt such innovative platforms and tools, thus, enhancing their communication strategies.

Cultural organizations need to open their virtual doors to the world and use ICTs in a more two way oriented approach than the way they do it nowadays. New technologies and social media need to be further adopted in the cultural communication process for creating meaningful experiences. In order for this to be better employed, cultural managers need to realize the value of marketing. In fact, Wymer, Boenigk, & Mohlmann (2015) have created a construct for nonprofit organizations as a guide for nonprofit marketing orientation that incorporates services, supporters, the creation of a brand of the cultural organization and commercial aspects for it. It would be thus, interesting to examine from a holistic communication and management perspective the services on offer by the cultural organization, its supporters and the identification of their needs and their characteristics, the elements that can create its brand that will make it well known to the public and commercial aspects. Social media and information technologies have a role to play at the management and communication level of the organization.

Another future research opportunity can be associated with human resources, cultural organizations and the implementation of information and communication technologies. Are cultural organizations willing to correspond with users on the online level? Little research has illustrated so far that on the one hand that there is low involvement from the user in the cultural organizations' accounts of social media, while cultural organizations do not correspond with their users, thus creating a two way communication with them is in need to be further examined (Lazzeretti et al., 2015). In that way, a vicious circle is created. Which is the case when employees of the cultural

organization are devoted to manage this online information directed to and from the cultural organization and interact with the users?

Mobile technologies allow for the interactive participation between the real and virtual worlds and this is where future research and cultural organizations should focus. They should be further researched in regard to their use as communication and promotional tools by cultural organizations but also in regard to their geographic implementation (Lee, Chung, & Jung, 2015; Thompson, Purcell, & Rainie, 2013) since research mainly takes place for the USA while results should be offered for other continents and countries.

CONCLUSION

ICTs that have brought forth the emergence of social media should adopt individually and within a specific framework social networks employing the best elements each one has on offer. Social media is growing rapidly and provide great opportunities for cultural organizations to enhance and reinforce the experiences they offer. However, the simple use of social media is not enough (Effing & Spil, 2016). They should organize and apply social media strategically to benefit (DiStaso & McCorkindale, 2013).

According to social media strategy' definition, it is "a goal-directed planning process for creating user generated content, driven by a group of Internet applications, to create a unique and valuable competitive position" (Effing & Spil, 2016, pp. 2). These new applications are taking into account the needs, preferences and expectations of various categories of public and encourage them to interact with the cultural content and context, as well as with other people, to share their experiences and memories, giving to community the sense of 'ownership' over culture. Fostering innovations with the implementation of the above mentioned technologies described in the chapter may allow for effective and efficient cultural management and cultural communication. Cultural managers

but also users may benefit from the implementation of emerging technologies towards a closer interaction with each other.

KEY TERMS AND DEFINITIONS

Cultural Communication: The application/adaptation of communication theories, mechanisms, methods and tools in cultural organizations.

Cultural Organization: A not for profit network that aims to promote culture and the arts.

Culture: The capacity of human beings to classify, codify, and communicate their experiences symbolically so that they can be available to future generations.

Mobile Media Technologies: Interactive use of computing devices such as smartphones or tablets that allow the user to communicate, interact, share and download material with the use of applications.

Social Media: Applications that engage people in sharing user-generated content employing online communication.

INTRODUCTION

The rise of information technologies and the Internet have dramatically changed the ways in which people interact, communicate and represent themselves and the world that they live in (Edwards et Al., 2013). In particular, the recent appearance of social network sites (SNS) is challenging mainstream social psychological research and it requires social psychologists to question their earmarking theoretical tools.

To date, social psychological research has mainly focused on the application of existing theories to explain the use and impact of SNS (de Rosa, 2012). Nevertheless, the convergence of social evolution and information technologies is laying a new basis for the performance of activities throughout the social structure (Castells, 1996:470-471), so that social psychologists must revise their theoretical traditions in its investigation.

Although research in the past decade has focused on the study of new phenomena generated by online social interactions, the underlying symbolic universe of meanings, products and contents of such interactions is still partially unknown.

Exploration of this semantic production can draw fruitfully on Social Representations Theory (SRT) (Moscovici, 1961/1976; 1995; Farr & Moscovici, 1984). In his classic study on the image of psychoanalysis Moscovici investigated

how different forms of knowledge encounter and cross-fertilize. His specific interest was in how scientific theories circulate within common sense and what happens to those theories when they are elaborated upon the laboratory of society. Moscovici identified the product of this encounter in social representations (SR), defined as common sense theories on key aspects of the world that allow individuals and groups to represent it and master it (Farr & Moscovici, 1984).

In this paper, we present and discuss the results of research on spontaneous conversations in SNS in two cultural contexts, France and Italy, which followed up on Moscovici's classic study on psychoanalysis. This research is part of a broader research project (de Rosa, 2011; 2012; 2013) comprising: a field study, content analysis of the online press and content analysis of spontaneous conversations on SN.

BACKGROUND

It is important to recall here that the conventional approach of social sciences to the study of SN has been rooted in the field of sociometry since the introduction and diffusion in the late 1960s of such well-known theories as the *six degrees of separation* and the *small world phenomenon* (Travers & Milgram, 1969). These theories have influenced generations of social scientists intent

DOI: 10.4018/978-1-5225-2255-3.ch608

on extending mathematical models to the study of social relationships in terms of network theory and relying on concepts such as nodes (individual actors within the network) and ties (relationships between those actors). Social network analysis (SNA) is the modern sociological evolution of this trend (Carrington, Scott & Wasserman, 2005; Scott, 2004). Thanks to the recent affirmation and visibility of the Web, this approach has become hegemonic in the study of SN (Catanese et Al., 2012; De Meo et Al., 2012).

On the one hand, this trend can be seen as the consequence of the increasing interest of social sciences in computationally intense methods with which to analyse and model social phenomena (Williford & Henry, 2012) leading to the reproduction of “‘habitual practices’ employed by quantitative researchers using the procedures which they are comfortable and familiar with” (Stoneman, Sturgis & Allum, 2012:854). On the other hand, it is possible to identify a significant lack of theory in the study of “what lies beneath” the massive and multiform production of social interaction in new online communication channels, especially from a semantic perspective (de Rosa, 2012).

Research on SR investigated via interpersonal exchanges on SNS may be a valid response to this theoretical challenge. In fact, in the 1990s, Moscovici (1995; 1997:7) provided an anticipatory proposal; he emphasised the importance of investigating new communication phenomena by studying “how common sense, the language exchanged, groups themselves are shaped in this cyber-communication”.

We accordingly assumed that exploration of the representational fields underlying the ‘social discourse’ would provide track of the new type of common sense emerging from SN, as well as the social positioning of different actors and groups.

Although there is no single definition of SNS (Boyd and Ellison, 2007; Nadkarni & Hofmann, 2011) we highlight a growing interest in their role in the social construction of knowledge

(de Rosa, 2013; Mazzara, 2008). Briefly, recent decades have seen a structural transformation of the traditional communication channels whereby tele-communication is used to connect people in a new pattern of “connected-presence” (Licoppe & Smoreda, 2005; Castells, Fernandez-Ardevol, Qiu & Sey, 2007), providing interactive commitment of the actors involved, be they scientists, trainees, or simply laypersons in the sharing of knowledge. In fact, ‘Science 2.0’ (Jankowski, 2002), along the lines of the recent web revolution (O’Reilly, 2005) implies a “coupling between science and ICT”, providing new ways “for accessing scientific knowledge and [...] participation” (Ponte & Simon, 2011:150).

The development in the knowledge building through technological innovation enlarges the discourse to relevant issues already developed in the literature like: the digital divide (Castells, 1996/2000) the ethical implications (Drude et al., 2008) the effects of online psychotherapies (Andersson et al., 2009; Shingleton et al., 2013). Regarding these issues, through the SN, the experts have the opportunity to open the doors of their rooms and meet laypersons, establishing social relationships and, most of all, a “familiarity” effect, generating “trust” (Markovà, 2009).

In the SN, the traditional view of media as a ‘dirty mirror’ of scientific theories is completely reversed. Not only can the public elaboration and understanding of science no longer be compared to traditional top-down communication flows (Castells, 1996/2000; Moscovici, 1961/1976), but it also gives way to a new form of coexistence, “whose transgression launches a process of creation of profane knowledge from what was originally a concept elaborated in the midst of a small group of researchers. Thus uprooted from its original context, the concept is appropriated by the different media and thrown around, discussed, amplified, acclaimed, distorted, disproved, discredited, forgotten and rediscovered, circulating in the process among all conceivable factions of society, serving each and every one in turn” (Bangerter, 1995:8).

In this sense, the choice of psychoanalysis is strategic. As suggested by Jesuino (2008:393) the investigation “would be much more problematic if the study focused on a hard science such as physics, which is more distant to daily concerns of common citizens. Psychoanalysis had, and still has, a rather ambiguous status within the scientific community.” In fact, although in 1961 Moscovici described psychoanalysis as “a cultural event that was no longer confined to the limited circle of the sciences, affecting the whole of society” (Moscovici, 1976/2008:xxix), its scientific status and therapeutic validity are still subject to discussion worldwide (Mecacci, 2000; Meyer, 2005; Onfray, 2010; Rowland Smith, 2010).

SPONTANEOUS CONVERSATIONS

Objectives and Hypotheses

In accordance with our theoretical perspective we present and discuss results from the analysis of spontaneous conversations collected from three SNS: *Facebook*, *Twitter* and *Yahoo! Answers*, in the French and Italian contexts. The SNS were selected on the basis of their distinctive aggregative characteristics and communication constraints reflected in the members' modalities of affiliation and segmentation, as documented in the literature (Greitemeyer, & Kunz, 2013; Ryan & Xenos, 2011; Nadkarni & Hofmann, 2011).

Free conversations among members of SN have been analysed from an ecological perspective of non-intrusive research in natural contexts. It is our conviction that a psycho-social approach, oriented to the investigation of semantic aspects (and not only the formal structure of relations among members), aiming to capture and analyse significant conversational excerpts from conversational co-production among SN' users, allow to go over the present sociological supremacy (influenced by mathematical and computer-science-based contributes) to the study of the structure and content of social networking (vs. the paradigm of SNA).

In particular, we explored:

1. The SR of psychoanalysis, psychiatry and mental-health emerging as interrelated systems of representations from online conversations on SNS;
2. The positioning of social actors, groups and communities on the basis of the SR shared;
3. The communication systems emerging from the user-generated content analysed according to different constraints characterizing each of the SNS considered.

In light of the main assumption – that the dynamic relation between SR and public issues in the new ‘social arena’ of SNS is likely to determine the symbolic positioning of groups with similar or conflicting interests and visions of the world (de Rosa, 2013) – the following hypotheses may be summarized in the capacity to identify:

1. Evidence of the co-existence of expert and everyday knowledge, science and common sense, ‘reified universes’ and ‘consensual universes’ with their specific processes and functions, that positions different user groups and styles of communication in specific SNS. These spaces give voice to and negotiate competing definitions of roles, forms of knowledge, practices and/or personal experience related to the domain of mental-health, among actors characterized by different levels of access and proximity to the objects of representations investigated, namely lay users, experts and experts in training;
2. The occurrence of different SR of the target objects (psychoanalysis vs psychiatry) according to the experiential/informative character of the conversational exchanges on *the SNS* as a function of their communicative constraints;
3. Cross-national differences in the SNS users' SR depending on their anchoring in the two cultural contexts (France and Italy) due to the media echo effect of the recent controversy

on the scientific validity of psychoanalysis and to the different legal and institutional frameworks;

4. Different communicational styles defined by the context of *Social Media* and specific aggregative and communicative attributes which differ considerably in regard to their members' patterns of affiliation and segmentation, constraints on the length of messages and their semantic context and emotional expressiveness, like the use of the SN as a *conversational space* for sharing and negotiating personal emotional/psychological problems and providing social support (the members of the SN as therapists).

Method

Data Collection and Sample

This exploration required a systematic and robust methodology for the retrieval and analysis of the semantic structures underlying the online user-generated content.

Consequently, we developed a search engine-assisted strategy for the collection of spontaneous public conversations among SN users, through Google Advanced Search (de Rosa, 2012; 2013).

This approach enabled us to access dialogues, conversational exchanges and discussions on the objects of analysis spontaneously produced in SNS rather than being affected by the researcher's mediation.

Conversations were collected over a one-year period (1/3/2010-1/3/2011). A set of keywords ('psychoanalysis', 'psychiatry', 'psychoanalyst', 'psychiatrist', 'mental-health', 'mental-illness') semantically related to the object of analysis, was employed in the search. All the posts appeared in Google Search, on the basis of the following criteria, are included in the statistical analysis: keywords, temporal window, SN and language (Italian and French).

In order to collect data we applied different steps (de Rosa, 2012):

Step 1: Open the web page www.google.it (or www.google.fr) and access to Google advanced search functions using the link located on the right of the search bar.

Step 2: Define the web search parameters in the specific language of interest.

Specify keywords in Google's "all these words" search bar. Specify the search language in the "Language" bar.

Limit the search to the domains of interest; i.e. for Facebook posts, specify: www.facebook.com in the "Domain" bar

Finally, leave the values of the other parameters as default, turn off - if activated - the SafeSearch filter, and click on the "Search" button to display the results.

Step 3: Limit the search to the pre-specified time frame, by using the function in the left column on the page displaying the results. Note that in our case we opted for a search for each month within the time frame of interest (i.e. "1/1/2010 - 1/1/2011").

Step 4: Opening of all the links obtained (one by one).

Step 5: Save pages in.html format, renaming them by title, page name, group name, discussion topic.

Step 6: Repeat the procedure using keywords composed of two or more words, phrases. The only difference with the previously indicated procedure, resides in the Google search bar in which to place these words, in this case corresponding to the following: "this exact word or phrase", and proceed with the instructions already explained above. However so, it is important to specify that in this case we had to proceed by utilising one phrase at a time, given the inherent characteristics to the logarithm of the search engine.

Twitter required to implement the following specific procedure through the Advanced Search feature:

in the first place, the search parameters remain unchanged, proceeding analogously to Step 1 as previously presented, taking care, however, not to specify in this case the web domain of interest; once obtained the results, to search in the Twitter domain, we used Google's "real-time" function (such function went off-line on July 2, 2011 after the deal with Twitter expired - reference: <http://searchengineland.com/as-deal-with-twitter-expires-google-realtime-search-goes-offline-84175>), located in the left column of Google's results page; Google in fact, automatically returned all Tweets related to the previously specified key-words.

In order to specify the time range, we used the time diagram in the right column of the real time results page, displaying results by month.

By clicking on each individual month, the search engine returned online tweets posted in that specific month. At this point, it was possible to save the Google search page in.html format, such a page including all tweets of interest.

Currently, via Google Trends you can collect interesting descriptive statistics on a theme starting from the following information: keywords, country and time period.

Social media sites have gradually spread over time; we recall in this regard some among those that are free: Socialmention.com; Tagboard.com; Hashtagify.me; Keyhole.co.

Socialmention favours some particular search sources ("wordpress", "ask" etc.) and by inserting the # symbol in front of the keyword it also allows to identify tweets; It also allows to select the time frame and language, with the added benefit of being able to investigate "sentiment" (the ratio of positive mentions against those that are generally negative) for each comment. Tagboard allows research on classical SN like Facebook and Twitter, viewing sentiment globally on the keywords selected, but not comment by comment.

In research, however, it is important to remind that most of the popular social SNS let crawlers extract data only through Their Own API (Application Programming Interface) so as to control

the amount of information about users and their activities.

Data Analysis

We employed an inductive and non-probabilistic approach to automated text content analysis (Lahlou, 2011). Specifically, co-occurrence analysis and descending hierarchical classification -four classes from the French corpus and three classes from the Italian one- were applied to the text corpora by means of the Alceste algorithm (Reinert, 1986) implemented in the *Iramuteq* software. *In particular, we took in account* the most relevant cited "words" in the descending hierarchical classification, selected on the bases of the chi2 value.

Results

Regarding the French context, Class 1 was the biggest (34.1%), followed by Class 2 (24.5%), Class 4 (21.2%) and Class 3 (20.1%). With regard to the Italian context, Class 1 was the biggest (51.2%), followed by Class 2 (37.2%) and Class 3 (11.6%).

The French Class 1 contained conversations mainly collected from *Facebook Pages* ($\chi^2 1802,4$) and related to psychoanalysis ($\chi^2 155,9$), mental-health ($\chi^2 46,2$) and psychoanalyst ($\chi^2 28$). In this class, the general topic of mental-health was prevalent, as testified by the occurrence of terms such as *disorder* ($\chi^2 274,2$), *depression* ($\chi^2 262,4$), *symptoms* ($\chi^2 203,2$) and *anxiety* ($\chi^2 126,6$). As expected, the language and the style emerging from the analysis of the sentences highlighted the presence of users characterized by high levels of expertise in the field, particularly groups and organizations, rather than private individuals, displaying specialized lexicons and information, in agreement with hypothesis a) -focused on position of different social groups in the SN-.

Moreover, we found a specific effort to delimit the boundaries between psychoanalysis and psychiatry in the field of psychopathology, particularly depression. Similarly, the Italian

Class 2 included conversations from *Facebook Pages* ($\chi^2 2276,3$) and to a lesser extent from *Groups* ($\chi^2 27,6$). Psychoanalysis ($\chi^2 260,7$) and psychiatry ($\chi^2 289,9$) were the main objects of discussion. *Psychiatry* ($\chi^2 321,3$) also represented the most relevant cited word in the class, followed by the terms *social* ($\chi^2 221,7$), *psychiatric* ($\chi^2 209$), *psychology* ($\chi^2 199,9$) and *patient* ($\chi^2 197,5$). Differently from the French context and in agreement with hypothesis c) (focused on cross-national differences) the representation of psychiatry and the domain of mental-health lay on a communitarian dimension, whereas intervention by professionals (professional educator) was centred on a rehabilitation process targeted on interpersonal and family relationships.

Again, specification of the boundaries of the psychiatric domain was subject to discussion. Formal and instructional language was used, although it focused on describing the methods and tools characterizing the relevant profession rather than providing diagnostic information on specific mental diseases.

As regards the representations identified -in line with hypothesis b- there emerged a difference between the SR of psychoanalysis and psychiatry in their approaches to mental-illness. In regard to the former, mental-illness was described in terms of a “painful psychic process” (French Class 1). By contrast, the latter conceived mental-illness as a “disease” requiring suitable treatment relying on diagnostic techniques and pharmaceutical methods (Italian Class 2).

Both French Class 2 ($\chi^2 168$) and 3 ($\chi^2 4599$), as well as the Italian Class 1 ($\chi^2 3181,5$), included conversations retrieved from *Yahoo! Answers*. The French Class 2 was focused on mental-illness ($\chi^2 183,5$) and mental-health ($\chi^2 14,5$).

Class 3 instead referred to the psychiatrist ($\chi^2 355$) and psychiatry ($\chi^2 31$) and also in the Italian Class 1 focused on the psychiatrist ($\chi^2 995,7$). Interestingly, the latter was also composed of sentences from *Facebook Profiles*, although to a lesser extent ($\chi^2 6$). Contrary to what was previously observed, the semantic field

of these classes seemed to reproduce a naive view of mental-health, once again in agreement with hypothesis a). The lexicon utilised included words pertaining to everyday language and especially linked to the emotions, actors and actions of ordinary social life and aspects regarding socialization: e.g. *love* ($\chi^2 269,8$), *man* ($\chi^2 193,5$), *eat* ($\chi^2 121,7$) and *wife* ($\chi^2 118$) in the French context and *life* ($\chi^2 167,4$), *speak* ($\chi^2 164,8$), *child* ($\chi^2 158,2$) and *friend* ($\chi^2 104,1$) in the Italian Class 1. Accordingly, the topic of mental-health was approached from a non-professional, heuristic perspective, in which users engaged in dynamics of experiential support rather than pointing out specific guidelines.

In the same vein, in the Italian Class 1, we found an emphasis on the role of peers and the family in situations of psychological distress, as conveyed by words such as *support* ($\chi^2 132,7$), *friend* ($\chi^2 104,1$), *person* ($\chi^2 86,3$) and *boy-friend* ($\chi^2 86$). In this case, users seemed to act as ‘infomediaries’ of expert knowledge, providing informal help and suggestions on choice of a therapist.

It was also possible to distinguish a representation of the psychiatrist in terms of ‘he who prescribes’ therapies, but ‘not enough’ to accomplish an adequate healing process, as opposed to a more functional psychotherapeutic intervention.

This medicalized representation of psychiatry was also present in the French Class 3. The word ‘psy’ ($\chi^2 773,9$) was the most important, followed by *doctor* ($\chi^2 647,5$), *drug* ($\chi^2 318,5$) and *psychiatrist* ($\chi^2 300,3$). To be noted is that this French expression is an effective and succinct way to express a single profile including many and differentiated professional jobs within (psychologist, psychoanalyst, psychiatrist...).

Interestingly, in this class the elements ‘doctor-ill-hospital’ could be identified with the axes of an epistemic triangle (Moscovici, 1961).

As expected (hypothesis c.) a basic difference in the conception of mental-health emerged in the two cultural contexts investigated. Whilst in France this domain was associated with the

practice of hospitalization and psychiatrists were institutionally given responsibility to control such state of individual 'deviance' in Italy professionals were expected to work within a dimension of socialization through schemes to rehabilitate the mentally ill within the community. These cultural differences – based on our hypothesis concerning the anchoring into the French and Italian legal and societal frameworks of the SR of mental-health and the relative social practices – highlight the interest of cross-cultural differences for studies on SN. They do so both from the perspective of content-knowledge building and meaning-sharing among the SNS users (including their representational systems) and from the perspective of shaping the use of technology. This assumption has been adopted by authors who have empirically demonstrated “that even more so than experience of use, culture is a key behavioural determinant” and on revisiting the behaviour chain model, have “found that even though users had to their disposal the same set of features, the uses for creating content and value and involving others and the time investment for staying active and loyal in the site differed across countries.” (Vasalou, Joinson & Courvoisier, 2010:727).

The French Class 4 comprised conversations from *Facebook Pages* ($\chi^2 787.9$) and *Groups* ($\chi^2 64.7$) and from *Twitter* ($\chi^2 52.3$). Psychoanalysis ($\chi^2 31.6$) and the psychoanalyst ($\chi^2 85.4$) were the main objects of discussion within this class. The semantic fields and the underlying representation of psychoanalysis were linked to the psychological and psychotherapeutic domains expressed through words like *psychology* ($\chi^2 371.3$), *health* ($\chi^2 370.7$), *psychologist* ($\chi^2 318.7$) and *psychotherapist* ($\chi^2 232.1$). Notably, in this case users mainly exchanged information on the training and career paths required to achieve the professional competence and status of psychoanalyst, thus introducing a discussion which negotiated the scientific boundaries of the discipline itself.

Similarly, the Italian Class 3 was based on posts retrieved from *Twitter* ($\chi^2 6963.9$), whereas mental-health ($\chi^2 2915.2$) and mental-

illness ($\chi^2 5318$) constituted the main objects of representations. In this case, the discourse focused on promotion of services and activities provided by local aid agencies through the words *mental* ($\chi^2 7493.2$), *health* ($\chi^2 6362.1$), *centre* ($\chi^2 200.6$) and *department* ($\chi^2 155$). Furthermore, the recurrence of Italian city names marked a common reference to specific local and community aid centres. Twitter was evidently employed as a marketing tool to exchange information and updates on services and initiatives, rather than being a 'room' for conversation.

Study of the communication systems underlying these online conversations yielded even more interesting findings. Because changes in communication systems are significant for studying SR, we assumed that the SNS investigated would implement specific aggregative and communicative attributes, differing considerably in regard to their members' patterns of affiliation and segmentation, constraints on the length of messages and their semantic context and emotional expressiveness (hypotheses a. and d.).

In particular, we found in Facebook Pages experts and institutions belonging to the field of mental-health that stimulated and contributed to discussions on the topic of mental disorders in order primarily to promote their expertise and 'advertise' their work and activities so as to provide primary support for persons who might resort to the Internet to find such information and support. The same objectives seemed to characterize communication on Twitter, although in this case it is not possible to speak of conversations, but rather of information exchanges and updates on initiatives and activities characterizing the agenda of professionals and agencies in the field of mental-health. Differently and interestingly, in *Yahoo! Answers* as well as in *Facebook Profiles*, psychological problems and disorders were contextualized in a sort of *mutual aid context* in which users, according to different levels of familiarity with expert knowledge, tried to share and negotiate information to support each other in identifying adequate remedies or professional

aid for precarious psychological conditions (in agreement with our hypothesis d.).

CONCLUSION

Finally, we sought to verify Moscovici's original hypothesis that the dynamic relation between SR and public issues in the new 'social arena' of SNS is likely to determine the symbolic positioning of groups with similar or conflicting interests and visions of the world (de Rosa, 2013). In our research we found a specific struggle for the definition of roles, forms of knowledge and practices related to the domain of mental-health negotiated among actors characterized by different levels of access and proximity to the objects of the representations investigated. On the one hand, we found lay users asking for advice and information from the community, specifically about specialist and professional services in the field of mental-health. They were frequently re-directed to instances of support and aid by the online community, so that scientific mediation was replaced with mutual

Figure 1. The psychologist and the SN

understanding. In this framework, professionals are even averted through denouncing their pointlessness competence, in view of a relative distance from 'real' life and everyday 'common' experiences.

On the other hand, posts produced by professionals in the mental-health field emphasised their

THEORETICAL FRAMEWORK	THE RESEARCH IN SHORT		
	OBJECTIVES	HYPOTHESES FOCUSED ON	MAIN RESULTS
We focus the interest of promoting researches on social representations, which take account of new arenas for social transmission and elaboration of knowledge through social exchanges among the members of the thinking society. (Moscovici, 1961/1976). Co-production among social networks' users, allow to go over the present sociological supremacy (influenced by mathematical and computer-science-based contributes) to the study of the structure and content of social networking (vs. the paradigm of Social Network Analysis, SNA) (Carrington, Scott & Wasserman, 2005).	To explore: - the social representations of psychoanalysis, psychiatry and mental health emerging as interrelated systems of representations from online conversations on SNS; - the positioning of social actors, groups and communities on the basis of the social representations shared; - the communication systems emerging from the user-generated content analysed according to different constraints characterizing each of the SNS considered.	a) position of different social groups in the SN.	a) The French Class 1 contained conversations mainly collected from Facebook Pages (chi2 1802,4) and related to psychoanalysis (chi2 155,9), mental health (chi2 46,2) and psychoanalyst (chi2 28). In this class, the general topic of mental health was prevalent, as testified by the occurrence of terms such as disorder (chi2 274,2), depression (chi2 262,4), symptoms (chi2 203,2) and anxiety (chi2 126,6). As expected, the language and the style emerging from the analysis of ECUs highlighted the presence of users characterized by high levels of expertise in the field, particularly groups and organizations, rather than private individuals, displaying specialized lexicons and information. The topic of mental health was also approached from a non-professional, heuristic perspective, reproducing a naive view of mental health. The lexicon utilised included words pertaining to everyday language and especially linked to the emotions, actors and actions of ordinary social life and aspects regarding socialization: e.g. love (chi2 269,8), man (chi2 193,5), eat (chi2 121,7) and wife (chi2 118,0) in the French context and life (chi2 167,4), speak (chi2 164,8), child (chi2 158,2) and friend (chi2 104,1) in the Italian Class 1.
		b) differences between the social representations of psychoanalysis and psychiatry in their approaches to mental illness.	b) As regards the representations identified, there emerged a difference between the social representations of psychoanalysis and psychiatry in their approaches to mental illness. In regard to the former, mental illness was described in terms of a "painful psychic process" (French Class 1). By contrast, the latter conceived mental illness as a "disease" requiring suitable treatment relying on diagnostic techniques and pharmaceutical methods (Italian Class 2).
		c) cross-national differences.	c) the Italian Class 2 included conversations from Facebook Pages (chi2 2276,3) and to a lesser extent from Groups (chi2 27,6). Psychoanalysis (chi2 260,7) and psychiatry (chi2 289,9) were the main objects of discussion. Psychiatry (chi2 321,3) also represented the most relevant cited word in the class, followed by the terms social (chi2 221,7), psychiatric (chi2 209), psychology (chi2 199,9) and patient (chi2 197,5). Differently from the French context and in agreement with hypothesis c) the representation of psychiatry and the domain of mental health lay on a communitarian dimension, whereas intervention by professionals was centred on a rehabilitation process targeted on interpersonal and family relationships: These cultural differences – based on our hypothesis concerning the anchoring into the French and Italian legal and societal frameworks of the social representations of mental health and the relative social practices – highlight the interest of cross-cultural differences for studies on SN.
		d) different communicational styles defined by the context of Social Media.	d) In particular, we found in Facebook Pages experts and institutions belonging to the field of mental health that stimulated and contributed to discussions on the topic of mental disorders in order primarily to promote their expertise and "advertise" their work and activities so as to provide primary support for persons who might resort to the Internet to find such information and support. The same objectives seemed to characterize communication on Twitter, although in this case it is not possible to speak of conversations, but rather of information exchanges and updates on initiatives and activities characterizing the agenda of professionals and agencies in the field of mental health. Differently and interestingly, in Yahoo! Answers as well as in Facebook Profiles, psychological problems and disorders were contextualized in a sort of mutual aid context in which users, according to different levels of familiarity with expert knowledge, tried to share and negotiate information to support each other in identifying adequate remedies or professional aid for precarious psychological conditions.

engagement in re-definition of their identities and the borders between 'expert' knowledge and common sense. They symbolically 'opened the doors of their rooms' through participation in the online discussion, harmonizing presences, styles and lexicons on the basis of the new communication patterns required by these web environments.

Briefly, in this new communicative scenario the results of our study show how different target groups act new practices, showing their positioning:

- Users act as 'infomediaries' of expert knowledge, providing informal help and suggestions online;
- Experts open the doors of their "physical-rooms" to "cyber-rooms".

Echoing the famous words of Woody Allen: "Psychoanalysis is a myth kept alive by the sofas", meaningful results from our research show how the "sofa" has moved in the recent decade "from the psychoanalyst's couch to SN". These are the new "living rooms" – in a cyber world (de Rosa, 2004) – where the familiarity effect induced among the SN members, who perceive themselves as "clubs of friends", contribute also to redefine the borders between the expert's knowledge, the professional's role aimed at the intervention and the lay people's social discourse around psychoanalysis and psychiatry.

FUTURE RESEARCH DIRECTIONS

Even if taken as a specific inquiry on SNS, we consider our research to be a preliminary step in the study of the semantic production of social-interactive phenomena generated by the ongoing global redefinition of patterns of communication and it is our conviction that further research in the field is warranted. We have shown how studies of social media can inform and be informed by, the concept of SR and its inseparable and constitutive role of communication.

KEY TERMS AND DEFINITIONS

Facebook: Free social networking service. Activated in 2004, it registered about 100 million users in less than 9 months.

Google Advanced Search: The most popular and currently the most used web search engine.

Social Networks: In the definition of social networks, inter-relationality among diverse social actors, such as individual private users and organizations, is a core element.

Social Representations: Common sense theories on key aspects of the world that allow individuals and groups to represent it and master it.

Twitter: Free social network and micro-blogging service that gives its users a personal page that can be updated by means of text messages with a maximum length of 140 characters.

User-Generated Content: Any form of content such as blogs, forums, posts, chats, tweets... created by users of an online system or service, often made available via social media websites.

Yahoo! Answers: Community-driven question-and-answer (Q&A) site launched by *Yahoo!* in July 2005.

The Internet Behavior of Older Adults

Elizabeth Mazur

Michelle Hough

Pennsylvania State University, USA

INTRODUCTION

Internet activities of persons over age 65 include communication (i.e., email, instant messaging); social media (i.e., Facebook, LinkedIn, Twitter), search engines (e.g., Google), online newspapers (e.g., nytimes.com), magazines (e.g., salon.com), discussion forums, classifieds (e.g., craigslist.org), photo sharing (e.g., Flickr), online banking, and bill paying. Most studies on this topic (i.e., Choi & DiNitto, 2013; Madden, 2010) have concentrated on email, texting, web surfing, banking, shopping, and more recently, social media, and are notable for being conducted by researchers in fields as diverse as psychology, business, communications, social work, gerontology, computer science, engineering, and robotics.

Although this entry emphasizes research with persons over age 65, some studies exclude age information, preferring instead the phrases retirees (Hahm & Bikson, 1989), senior citizens, or, as in one early publication (Edwards & Engelhardt, 1989), members of AARP (age 50 and over). Publications that do specify participant age often group together persons differing in age by as much as 30 to 40 years (e.g. Trocchia & Janda, 2000; Zhang & Kaufman, 2015), inconsistently define *older adult* as beginning at ages 55 (i.e., Wong, Yeung, Ho, Tse, & Lam, 2014; Zhang & Kaufman, 2015), 59 (e.g., Berner et al., 2015;), or 60 (i.e., Choi & DiNitto, 2013), or do not specify age distribution past the defined minimum age

(i.e., Reisenwitz, Iyer, Kuhlmeier, & Eastman, 2007; Zhang & Kaufman, 2015).

BACKGROUND

The earliest publications concerning older persons' Internet behaviors – before the word *Internet* was ever used – speculated that technological solutions, connected computers included, could improve the daily lives of older persons in their homes and communities. Theorists initially centered their attention on two-way communication, especially to mitigate perceived loneliness. For example, Ramm and Gianturco (1973) envisaged a “picture communication system with the aid of computers” (p. 325) that could personalize entertainment, education and home employment in order to fight isolation and feelings of uselessness.

As editor of a special issue of *American Behavioral Scientist* on technology and aging, Monk (1988a, 1988b) emphasized the significance of networked communication to the isolated elderly and argued that the elderly are often active users of technology rather than passive recipients. In 1989, Edwards and Engelhardt (1989) explicitly introduced the concept that older persons are not necessarily technophobic. The self-selected college-educated survey respondents over age 50 were generally positive about computers, notably in terms of a short-term change in attitudes as a result of their brief supervised technology experience.

rience and interest in Internet-related computer use for health insurance benefits, personal and family medical history, genealogy, and stock market information. In a comparison of retired and employed computer inexperienced public utility workers in California, Hahm and Bikson (1989) found that email increased interactions among retirees, though, according to the authors, “older adults must be given multiple sources of instruction” (p. 127).

OLDER ADULTS AS ACTIVE INTERNET USERS

Fortunately, a growing body of theoretically informed, empirically based literature, still mostly focused on electronic mail, began appearing in the 1990s. Beyond their specialized foci, research in this area underscored that the elderly are active users of technology, more capable of understanding and enjoying the Internet than was originally assumed.

The Pew Research Center Describes the “Gray Gap”

Beginning with its initial survey of the “gray gap” between young and older Americans (Lenhart, 2000), Pew Internet & American Life Project consistently has recounted that Americans age 65 and older are among the least likely groups to go online; once online, however, they are typically enthusiastic emailers, information searchers, and social networkers.

Why have older persons been less likely to go online? Initially, few persons over age 65 had Internet access (Lenhart, 2000), partly due to many being retired and some living on fixed incomes. However, economic factors never by itself explained the age differential. A second major factor was lack of contact with computers, and this was true even for older Americans with college or graduate degrees. As detailed by Fox (2004), most older persons lived lives far removed from

the Internet, knew few people who used email or surfed the Web, and could not imagine reasons for spending money and time learning how to use a computer. In addition, Fox (2004) reported that persons over 65 were more likely than any other age group to be living with disability, which could hinder their ability to obtain computer training or read the small type on many Web sites.

Since the initial 2000 report, each subsequent Pew paper has described an increase in older persons’ Internet use, especially between 2000 and 2004, when Fox (2004) reported a 47% jump. In 2001, Fox enumerated the top Internet interests among seniors who go online to include mainly email, but also hobby information, news, health information, browsing “just for fun,” and weather updates. By 2010, although users age 65 and older were still primarily using email to maintain personal contacts, 13% - more than three times as many as in 2009 - were relying on social media to manage their daily communications – sharing links, photos, videos, news and status updates (Madden, 2010). By 2013, the percentage of social media users had jumped to 27%. Yet, older computer users are still significantly less likely than all American adults (63%) to use social networking sites (Smith, 2014). According to Duggan (2015), of the five major platforms of current social media, Facebook is the most popular among older adult Internet users (48%), though they are less likely to go on Facebook than all U.S. adult Internet users (72%). Connected older adults also use – though less frequently – the social media platforms Pinterest (16%), LinkedIn (12%), Twitter (6%), and Instagram (4%). Relatively few older wired users participate in other online platforms such as discussion forums (8%) and Tumblr; only 2% of Internet users ages 65 and older report doing so (Duggan, 2015).

Since 2000, wired seniors consistently have been more likely than their offline peers to be younger, married, white, highly educated, and enjoying relatively high incomes; recent data confirm this trend (Smith, 2014). Lenhart and Duggan (2014) noted some interesting behaviors

among older Internet users in committed relationships; almost half (47%) reported sharing email accounts with their partner, as compared to 27% of all Internet users who were married or in a committed relationship. Older users' sharing of social networking profiles was less frequent (11%), and unlike email account sharing, there was little age variation in this behavior (Lenhart & Duggan, 2014).

Gender differences in Internet usage have been inconsistent over the years. Although in 2000 about 40% of older Internet users were women, in 2004 the gender ratio among U.S. wired seniors appeared to have reached parity, similar to the general Internet population. However, recent data indicates that almost two-thirds (65%) of men ages 65 years and older use the Internet or email as compared to 55% of women (Smith, 2014). Interestingly, whereas disability initially may decrease computer use, more recently older adults living with chronic disease have been increasingly likely to state that they work on a blog or contribute to an online discussion, a listserv, or another Internet forum that helps people with personal issues or health problems (Madden, 2010). According to Smith (2014), older adults with physical challenges often enjoy tablets and e-readers, but at a rate that is somewhat lower (22%) than those without health or disability issues (30%).

There is a burgeoning group of Americans who are slightly younger than retirees and who are more attached to the online world. This "silver tsunami" has gained momentum through the past decade. Internet users age 65 or older are often cited as the fastest-growing demographic group online, but that description can be misleading. Much, though not all, of the growth in this age group over the past decade has come from long-time Internet users aging into senior status rather than from waves of elderly nonusers in their seventies and eighties suddenly going online. Current data indicate that after ages 65-69, Internet and broadband use decreases with age and falls off most dramatically starting at about age 75 (Smith, 2014). At the same time, data indicate that most

older adults who become first-time Internet users in their senior years become enthusiastic users, going online daily or almost every day (Smith, 2014).

Does Use of the Internet Improve Older Adults' Social Involvement and Quality of Life?

The first longitudinal study to examine causal relationships among use of the Internet, social involvement, and psychological consequences suggested potential drawbacks to Internet use, although older persons do not appear to have been included. Kraut and his colleagues (1998) tracked participants longitudinally, and over 12 to 24 months, disturbing trends were identified. Increases in Internet use predicted less communication within the family and more loneliness and depression. The initial reactions in the press were not surprising ("Sad, Lonely World Discovered in Cyberspace"; Harmon, 1998); however, Kraut's research team later found that the negative effects did not persist over longer periods of time (Kraut et al., 2002). Nonetheless, research continues to suggest that there could be social and emotional drawbacks to Internet use. For example, Stepanikova, Nie, and He's (2010) large cross-sectional study of U.S. adults ages 18 to 70 showed negative impacts on interpersonal interaction, communication, loneliness, and life satisfaction. These hypothesized consequences are sometimes called *displacement*; the Internet replaces presumably more meaningful face-to-face interactions (Huang, 2010).

The implication that Internet use might lead to social isolation is problematic for older adults, at least in the US, given their high risk for depression, especially for those who experience loneliness and lack social support (e.g., Seritan, McCloud, & Hinton, 2009). Yet, it is possible that Internet communication actually might facilitate social networks among those who are geographically dispersed (Stepanikova et al., 2010). Early research in the US did suggest significant benefits of computer use for older adults. For example,

White and colleagues (1999) taught retirement community members (average age 77 years) to operate computers for word processing, accessing the Internet, and email. There was an immediate post-training improvement in feelings of loneliness among the 15 computer users compared to the eight members of the control group, but this difference was not significant at the five-month follow-up.

In a review of the literature provocatively titled “Computer use has no demonstrated impact on the well-being of older adults,” Dickinson and Gregor (2006) outlined several reasons supporting their thesis. One problematic issue identified was that many of the intervention studies did not control for variables that likely accompanied computer instruction, such as face-to-face interactions. The authors also noted a tendency for small or even nonsignificant effects to be considered *improvements* when summarized in subsequent research. Finally, Dickinson and Gregor (2006) recognized that individuals whose well-being is higher initially are more likely to successfully learn to use computers and are less likely to drop out.

Recent research using large samples, longitudinal data, and mediational models, as well as reviews and meta-analyses, suggests that there are likely no major negative consequences of Internet use for older adults, and there may be some benefits. The least positive recent report was in a meta-analysis by Huang (2010), who examined the relation between measures of psychological well-being and Internet use. Although Huang found a very small association between greater Internet use and reduced well-being, a major limitation Huang cites is that only 7.5% of the participants were adults over age 55. On the positive side, Chang and colleagues (2015) studied adult Facebook users in the U.S. Younger adults had more Facebook friends, but increasing age was associated with a higher proportion of Facebook friends that were actual friends beyond the Internet. Across all ages, having a higher proportion of actual Facebook friends was associated with lower reports of loneliness.

Cotton and colleagues have conducted several recent studies suggesting positive impacts of Internet engagement on older adults. Initially, the researchers studied residents of communities for aging persons in one U.S. state (Cotton et al., 2013). Although the sample was not diverse and predominantly female, it is notable for having an average participant age of 83. The major positive result was that even after controlling for possible confounding factors, greater Internet use was correlated with lower depression. A longitudinal study with a larger sample size by Cotton and co-authors (2014) similarly showed a reduction in depression in older adults associated with higher Internet use, with a stronger effect for individuals living alone. Thus, taken together, the research studying Internet engagement and psychological well-being suggests that Internet use is unlikely to cause great harm, and shows promise for conditions such as depression.

OBSTACLES TO OLDER ADULTS' INTERNET USE

The three most common barriers to older adult computer use cited in the literature are physical disability, cognitive limitations, and negative attitudes towards computers.

Physical Limitations

Common recommendations to ameliorate physical issues that may impact older adults as well as younger persons with disabilities include using large fonts, providing visual contrast, and minimizing actions such as scrolling that might be impacted by physical difficulties (Charness & Boot, 2009; Kim, 2008). Novice users perform better with input devices that allow direct interaction with the screen; persons with severe mobility problems typically do best with voice input (Fisk et al., 2004). Computer programs and systems now often include such accessibility features that users can activate when needed (Kim, 2008),

and websites have improved in ergonomic design (Nielsen, 2013). Recent tests by Nielsen (2013) showed that computer users over 65 performed better than previous cohorts, but still had more challenges than those under 55. On all measures (success, speed, errors, satisfaction), older users performed more poorly. Visual issues were one problem, with tiny text or poor contrast causing difficulties; another was what Nielsen calls “unforgiving” design, such as forms that cannot handle minor typos or hyphens in phone numbers. Larger mobile devices may help overcome some of these issues. Smith (2014) reports that 27% of older users own a tablet, an e-reader, or both, more than the 18% with smartphones.

Cognitive Limitations

Research has suggested that older computer users are likely to be slower to learn how to operate computers and their programs and that they will commit more errors in doing so (Charness & Boot, 2009; Kim 2008; Nielsen, 2013). Some of these problems may be due to declines in working memory, problems in regulating attentional processes, lesser abilities to form new procedural knowledge, difficulties in multitasking, and movement difficulties that impact the ability to respond to commands or use computer program menus and other interface elements (Fiske et al., 2004). Rogers and Fisk (2010) concluded that the challenge is translating knowledge of people’s potential limitations into universal design.

Much attention has been given in recent years to the question of whether computer gaming can ameliorate cognitive decline. At present there are no clear answers. The online “brain training” site, Luminosity, recently had to refund its customers because the company made unsubstantiated claims that the games could improve cognitive functioning and reduce dementia risk (Span, 2016). There have been numerous failures in recent empirical work to find positive effects of online games on cognitive functioning. A meta-analysis by Powers and colleagues (2013) did indicate some

experimental evidence of positive impacts on older adults, but the domain affected most was motor skills.

Attitudes

Research examining the attitudes of older computer users has been difficult to interpret. Although some studies have shown improved attitudes towards computers after training (Kim, 2008), it cannot therefore be assumed that older persons’ negative attitudes towards computers cause computer or Internet avoidance. Nonetheless, older users remain “slower to adapt to new technologies and more likely to report anxiety...or frustrations” (Rogers & Fisk, 2010, p. 647). Researchers also report older adults’ difficulties in learning as well as the lack of availability of in-person help and access to computers and technology (Chen et al., 2013). However, because these studies lack employed older persons, who are more likely to have computer experience, the challenge for researchers lies in disentangling computer knowledge (and, relatedly, computer experience) from factors such as income, education, and health status.

Little attention has been given to the issue of older users’ knowledge of computer security. Grimes, Hough, Mazur, and Signorella (2010) examined the relationship of age to knowledge of various Internet hazards among 167 US adults ages 19 to 91 years. Older persons (average age 72) showed less knowledge of Internet hazards, such as viruses and spam, than did younger individuals (average age 24). Among the older adults, however, education and prior computer experience were more important in predicting Internet security awareness than were age and gender.

Thus, much of the research suggests that older persons may be more vulnerable to the difficulties that typically plague all computer users, such as horizontal scrolling, inconsistent controls, complex security rules, and other basic design flaws. Yet bad design and complexity may be particularly problematic for the oldest, especially when combined with their higher likelihood of being

computer novices; these challenges may impact confidence and persistence.

CONSUMER IMPLICATIONS OF OLDER ADULTS' INTERNET BEHAVIORS

The consumer implications of older adults' Internet usage have been considerable, at least in the US. According to Roberts and Manolis (2000), age is the most important demographic characteristic for consumer marketers and researchers. Kamal and Patil (2003) note that many older adults in the US are rich in both time and money (see also Hough & Kobylanski, 2009). Yet the buying patterns and attitudes of this segment differ from those of younger consumers. Persons age 65 and older have been less likely than those ages 45 to 64 to use the Internet for online purchasing; in particular, those older persons who lack confidence in their Internet skills use it significantly less frequently (AARP, 2000).

From the results of interviews with 12 American men and women ages 57 to 87 years old, Trocchia and Janda (2000), identified differences between older Internet users and non-users. Expanding on that study, Hough and Kobylanski (2009) theorized that marketing interventions focused on placing technology in consumers' hands can be particularly useful in influencing older persons' reference group affiliation, nature of social relations, and perception of reality. They also noted that marketing focused on price or on special promotions have little to moderate impact on increasing older persons' engagement with computers or the Internet. According to results from surveys of 171 Americans between ages 65 and 85, Iyer and Eastman (2006) found that older persons' attitudes about the Internet were also affected by whether they felt that the Internet was fun, convenient, and efficient. Lee, Han, and Chung (2014) found perceived usefulness, enjoyment, and ease of use to be crucial factors in Internet adoption by mature users.

Reisenwitz and colleagues (2007) posited that other factors that impact the effectiveness of marketing to older consumers include emphasizing the ability to create nostalgic experiences online, promoting aspects of innovation, and addressing perceptions of risk. Bruine de Bruin, Parker, and Strough (2016) note multiple studies that indicate that older adults tend to search for fewer options and prefer limited selection sets as compared with their younger counterparts. Older adults are significantly less inclined to engage in intensive alternate searching with the goal of selecting the optional choice. These results suggest that older consumers are less likely to engage in prolonged on-line research sessions when making purchase decisions. Taken together, these studies indicate that the commercial implications of older adult engagement with the Internet continue to be challenging and complex.

FUTURE RESEARCH DIRECTIONS

The issue of whether the Internet will improve older adults' quality of life and social relationships remains unresolved, due partly to the lack of generalizability of many empirical findings. With the exception of studies from Pew Research Center, much of the research has ignored older persons living in private households, independently surfing the Internet. Researchers also often omit information concerning participants' gender, income, education, health, and employment status.

Despite the commercial advertisements, there are few experimental studies of computer gaming's possible link to reduction of cognitive decline in older adults. There is also little research on telehealth, which promises improved access to medical and psychological services, especially for persons with disabilities and older persons living isolated lives (Khubchandani & Thew, 2016). There is a paucity of cross-cultural research, especially in the global south, where promoting Internet access to resources and fostering social inclusion may be more important than in the west, where most of the research has been completed.

CONCLUSION

As Ogozalek (1991) first predicted in an early review of the impact of computer technology on aging, cohort effects complicate prediction from one age group of older adults to another. Charness and Boot (2009) have questioned whether the “gray gap” in both computer and Internet use described over a decade ago (e.g., Lenhart, 2000) will ever be completely eliminated. Current research still has not answered whether the ongoing pace of change in technology, combined with changes associated with aging, may mean that there will always be fewer older than younger adults using the newest technologies. However, as current Internet users in their 50s and early 60s age into the senior population, they are likely to maintain positive attitudes towards technology and continue frequent use, which the research suggests may benefit mental health and social relationships.

KEY TERMS AND DEFINITIONS

S

Accessibility: The goal of making any place or process usable by individuals with disabilities or challenges; in this context, making the Internet and computer technology usable for older adults with physical or cognitive limitations.

Brain Games: Video games, usually online, hypothesized to keep brain functioning at levels of younger individuals.

Gray Gap: Refers to data that indicates that older adults are less likely than those under 55 to be online.

Marketing: Techniques used to encourage consumers to make purchases.

Psychological Well-Being: Usually operationalized in terms of mood or interpersonal functioning; lower wellness would be reflected in indicators such as depression, loneliness, or social isolation.

Silver Tsunami: Phrase referring to the large number of rising seniors in many world economies.

Telehealth: The use of electronic information and telecommunication technologies to support long distance clinical health care and health education.

Issues and Challenges in Enterprise Social Media

Sarabjot Kaur
IIT Kanpur, India

Subhas Chandra Misra
IIT Kanpur, India

INTRODUCTION

Social media is a ubiquitous phenomenon enabling social connections worldwide. This communication platform has given rise to a new social order wherein users can create and disseminate information, opinions, self-created content and knowledge to widespread audience. Business organizations are also catching up with the phenomenon in terms of utilizing the functionality of social media tools for intra firm communication among employees for enterprise wide social networking and collaboration (Fulk & Yuan, 2013). Many organizations are using Enterprise Social Media (ESM) tools for information sharing, crowdsourcing ideas and solving problems, and relationship building (Riemer & Scifleet, 2012). The present article attempts to understand the enterprise social media tools from the perspectives of its functional and interactional aspects along with highlighting the key issues associated with its usage.

BACKGROUND

Social media provides a platform to create and share user generated content along with the functionality of connecting with people. Facebook, Twitter and LinkedIn, wikis, blogs etc. are some examples of popular social media tools. Users can look for people with similar interests, connect with them, create groups and share varied types of content. Web tools similar to popular social media

are being utilized in the enterprise context to foster collaboration and knowledge sharing within the firm. These tools are known by varied names such as Enterprise Social Media (ESM) or Enterprise Social Software Platforms (ESSP).

Defining Enterprise Social Media

Leonardi et al. (2013) define Enterprise Social media (ESM) as “Web-based tools that allow workers to communicate messages with specific coworkers or broadcast messages to everyone in the organization; explicitly indicate or implicitly reveal particular coworkers as communication partners; post, edit, and sort text and files linked to themselves or others; view the messages, connections, text, and files communicated, posted, edited and sorted by anyone else in the organization at any time of their choosing” (p.2). According to Boyd and Ellison (2007), these are “web-based services that allow individuals to construct a public or semi-public profile within a bounded system; articulate a list of other users with whom they share a connection; view and traverse their list of connections and those made by others within the system”(p. 211).

ESM includes tools like as blogs, social network sites (SNSs) and wikis. A lot of different packages are available for use by enterprises. SharePoint by Microsoft, is an online application platform where members can collaborate for team projects, upload and modify files, initiate discussions and work together in a virtual space mak-

ing the collaborative work easier to execute and monitor. Jive is another name in the same list that provides functionality of enterprise wide connections facilitating online sharing and collaboration among employees across the world. Other tools in use are Yammer and Chatter.

Benefit of ESM Tools

ESM provides an ability to maintain social connections along with accessibility to digital content (Kane, 2015). It gives a way of connecting with employees across the organization facilitating interactions and information sharing. Online connections, social interaction and communication patterns can reveal a lot about the various knowledge communities in the organization. Along with providing a functionality similar to traditional media of communication exchange such as email, it provides a way to connect and display the shared information to a preferred set of people who can further benefit from the exchange. The mutual communication partners, shared information and membership of different online groups can help employees understand the prevalent social dynamics along with locating the relevant support for knowledge (Ellison et al., 2015).

Some of the major benefits are listed below.

Acts as an Interactive Platform

Members of an ESM platform can interact in a variety of ways. Subramaniam and Nandhakumar (2013) identified the following ways in which members interact over an ESM platform

1. **Impromptu or Informal:** Ad-hoc problem solving is enabled by collective work of individuals in an Informal way where formal structures do not inhibit communication and interaction. Members come together to work on some common problem that needs immediate attention.
2. **Planned:** This happens in the duration of a planned project where the interaction is

sustained for specific information needs from different members of the community.

3. **Ongoing:** Focused and repetitive interactions help in developing roles as members share knowledge over ESM platform.

Helps to Locate Knowledge Source within Organization

Awareness about the communications of others can help the knowledge seekers understand the potential knowledge sources. An understanding of who knows what and who knows whom helps the employees become aware of the communications among the coworkers and it becomes imperative in eliciting knowledge from them whenever required. This kind of awareness has been referred to as 'ambient awareness (Leonardi & Meyer, 2015) which is facilitated by the use of enterprise wide social media tools. Message transparency and translucent network connections offered by social media (Leonardi, 2015) give employees an edge over the opaque communications handled by conventional technologies.

- Message transparency is the ability of users to see the different conversation threads and the contents generated therein.
- Network translucence or the knowledge of people's communication partners helps in identifying real communication patterns in any organization which may be different from the traditional or expected ones.

Employees can gain an understanding about the nature and kind of projects done by their colleagues along with their individual expertise. The communication threads and patterns can be observed to make sense of individual's tacit knowledge which can be accessed whenever required.

Facilitates Knowledge Sharing Among Employees

Social tools enable knowledge sharing and collaboration which is important for the new and

creative ideas to emerge and a sufficient flexibility of sharing information across the organization provides a foundation for such an activity (Patroni et al., 2015; Subramaniam & Nandhakumar, 2013). Knowledge sharing is an equivocal concept involving a communicative process affected by social dynamics and interpersonal processes. It can be a difficult process in case of geographically dispersed organizations as employees may not be aware of the right source of getting advice and expertise. In such a case, ESM allows employees to connect with their counterparts working in dispersed locations across organization and hence help them to access knowledge from the right source and person. (Ellison et al., 2015).

Facilitates Collaborative Work

ESM tools enable collaborative content generation. It fosters collective intelligence which is a source of new ideas and creative solutions. Capability of sharing knowledge and expertise allows creativity to flourish as it enables the combination of varied perspectives and enables the completion of collective work within shared timeframes (Subramaniam & Nandhakumar, 2013). Virtually co-present actors are bound by focused interaction with other actors in real time to create an interaction order which facilitates collective work (Subramaniam & Nandhakumar, 2013). ESM helps in crowdsourcing solutions for problems by facilitating the provision of diverse information from various sources in the organization (Mäntymäki & Riemer, 2014).

ISSUES IN ESM USAGE AND KNOWLEDGE SHARING

ESM tools act as enabling technology providing a means for the desired ends like collaboration, networking and knowledge sharing across enterprises. However, its actual usage in different contexts may be varied. There are a number of factors that have an impact on knowledge sharing via ESM tools

and subsequent employee performance, some of which are listed below.

Inter vs. Intra Team Usage

Teams have their own peculiar demands w.r.t. task requirements. The kind of information required by the members of a team varies with the context of interaction. Hence, ESM usage in inter-team and intra-team context has different effects on knowledge sharing. The former is more suited for innovative performance associated with finding new knowledge and the latter is more suitable for task performance using knowledge for short term use without any consideration for discovering novel information (Kuegler et al., 2015). Thus, task context is an important aspect to be taken into perspective while assessing the role of ESM in employee performance.

Cultural Norms

Cultural norms of the organization play a significant role in defining the mindset of the employees to collaborate. Competition for better performance and sharing can also motivate employees to read and explore more about a given area. Both collaboration and competition facilitate knowledge sharing leading to faster learning among employees (Patroni et al., 2015).

Tie Strength

Social ties are connections among people which are used to share varied information with tie strength being strong, weak or absent in any given social circle. Granovetter (1973) defined tie strength as “a combination of the amount of time, the emotional intensity, the intimacy (mutual confiding), and the reciprocal services which characterize the tie” (p. 1361). In context of knowledge sharing, social ties and their strength affect the behavior of knowledge seeker and provider. In case where initial ties are strong and knowledge is less complex, there exists a greater possibility that knowledge will be sought

right away (Leonardi & Meyer, 2015). However, the kind of knowledge sought also varies with different social ties. Strong ties have individuals with whom there is information overlap. Hence, weak ties may generate information that is novel (Granovetter, 2005).

Cognitive Overload

Employees all across the organization may exchange different kinds of information interacting over ESM tools. This leads to increased load or volume of communication. Hence, it may be difficult to keep a track of all relevant communication and conversation threads. Also, there is a disadvantage if there are too many conversations going on as people may fight for attention. In such a case, the aim of reducing an employee's knowledge search efforts by developing a contextual understanding of the knowledge sources may not be fully achieved (Leonardi, 2015).

CHALLENGES IN ESM DESIGN AND ADOPTION

Apart from the issues that arise in the usage of ESM tools in particular reference to knowledge sharing and collaborative work, there are certain challenges in its design and adoption which need to be addressed.

ESM Platform Design

Designing a platform requires the consideration of organizational conditions, culture and employee needs. Kane (2015) classified various aspects of platform design for enterprise social media. Different functionalities and design aspects present in the popular social media tools can be utilized in the context of designing a platform for enterprises taking into view their requirements and peculiarities. Some of the interaction and content related aspects identified by Kane (2015) are:

1. Persistence of relationship depicting the network boundaries w.r.t inclusion of various stakeholders in the organization wherein a decision has to be made regarding the inclusion of internal and/or external stakeholders like clients and vendors as well. Including external stakeholders may help in solving shared problems (Kane, 2015).
2. Types of connections which can be either interactions (messaging and chats), proximities (Digital proximities via forums and common online discussion) or flows (movement of information among non-connected users such as in case of Twitter hashtags).
3. Connection capabilities which may offer an option to understand the strength of social ties generated by binary connections and their interaction intensity.
4. Supported content may vary from simple text to audio, video and hyperlinks etc. along with the option of expressing one's opinion on information and posts shared with others.
5. Digital trace enabling a log wherein activities of members on the social media tools can be recorded and summarized for use by other members.
6. Profile authenticity aspect covers the extent of accurate representation of real identity of users who generate and share content thereby increasing its trustworthiness.

ESM tools can be designed in view of existing popular social media tools tailoring their basic functionalities as per organizational needs. Individual usage defines the way technology is understood and utilized in the long run. Users make sense of technology according to their own peculiar needs and may have differentiated usage. Thus, understanding user perspective at various phases in the ESM adoption and implementation can aid better design of the system with consideration of issues like intra-team and inter-team usage. Features like creating filters for eliminating the excessive information, social tie metrics based

on the conversational and exchange frequency etc. may be considered while designing different ESM tools.

ESM Platform Adoption and Usage

Any enterprise system is adopted keeping into view certain key organizational requirements along with assessing the system's compatibility with the idiosyncrasies of organization. In case of ESM tools, factors such as purpose of ESM, participants involved, legal and security risks along with governance and policy mechanisms (Turban et al., 2011) must be considered in adoption decision. Adoption of any enterprise system makes the system accessible and available but there are certain factors that influence its continued usage. On the individual level, self-construal and interdependent tendencies of employees should be taken into view (Liu & Rau, 2014) in respect of ESM tools for intra organizational usage. Employees engage in social sense making of ESM creating their own peculiar communicative practices over such media (Riemer et al., 2012). Utility of ESM can be enhanced by positive organizational factors in terms of conducive knowledge sharing culture and leadership support. Thus, various factors at technological, organizational and individual level are interrelated and their constructive interplay is necessary for ensuring successful assimilation and continued usage of ESM tools.

FUTURE RESEARCH DIRECTIONS

Enterprise social media is a relatively new area for scholarly research in information systems domain. It has previously been explored in context of its knowledge sharing, interactional and communicative consequences mediated by different organizational, technological and individual user related variables. However, a more holistic understanding

can be achieved by adopting a multi-perspective view of the phenomenon. For instance, the effect of organizational support in terms of leadership and supportive team culture may be explored in terms of its effect on knowledge sharing and organizational communication. In addition, user perspective may be understood in greater detail with the help of more qualitative studies that may aid in uncovering design related constraints which can be subsequently worked upon to create efficient tools suitable for organizational requirements. Constant connectivity on ESM tools may lead to a wide variety of information generating attentional conflict (Brzozowski, 2009). Apart from understanding the beneficial consequences of the ESM, future research can explore the effect of this attentional conflict generated due to excessive usage of ESM tools on knowledge sharing behavior of employees and subsequent work performance related consequences.

CONCLUSION

ESM tools have potential to foster collaboration and make information exchange easier. However, the successful assimilation of this technology requires support both at the organizational and individual levels. Technology in itself is a means. The ends to which it is eventually utilized rests on the user. Hence, organization needs to understand various dimensions of adopting and implementing ESM tools in phased manner allowing users to understand and make sense of it. Considering the interplay of various factors at organizational, technological and individual level can help in devising suitable plans for adoption and implementation. Effective usage of ESM can benefit organizations in terms of shared learning and cross-functional expertise in solving problems which can lead to enhanced innovative performance of the organization as a whole.

KEY TERMS AND DEFINITIONS

Collective Intelligence: Shared intelligence resulting from group efforts where group members collaborate and compete to reach consensus in respect of mutually relevant problem.

Geographically Dispersed Team: A team whose members are located at geographically distant places and employ collaborative web based tools to accomplish group tasks.

Knowledge Communities: Group of people sharing common interest who come together for generating and exchanging information and ideas on specific issues in an organizational context.

Knowledge Management: The practice of creating, recording, sharing and using knowledge generated within organizations for fulfilling organizational goals.

Sense Making: Process by which people understand and attribute meaning to experiences.

Social Ties: Individual connections maintained by people in their social circle within which they interact and exchange varied kinds of information.

Tacit Knowledge: Knowledge that results from internalized information and experiences and is difficult to explicate in a formal way.

User Generated Content: Content such as text, video, audio, images appearing on blogs, wikis, discussion forums and other social media websites created by users of these online services.

Mapping the Dissemination of the Theory of Social Representations via Academic Social Networks

Annamaria Silvana de Rosa

Sapienza University of Rome, Italy

Laura Dryjanska

Sapienza University of Rome, Italy

Elena Bocci

Sapienza University of Rome, Italy

INTRODUCTION

Academic social networks are forms of Internet service, which facilitate the management of relations among scientists, sharing resources for publications, and in some case data, research results and multimedia sources. This chapter concentrates on what are the benefits of academic social networks, how to analyze their impact in spreading knowledge and why they are important. In particular, it aims at mapping the presence of publications using the case study of the theory of social representations in three academic social networks: Academia.edu, ResearchGate and Mendeley.

Academia.edu was founded in September 2008 by Richard Price, who did a PhD at Oxford in philosophy. After finishing his PhD, he founded Academia.edu, which is a platform for academics around the world to connect and share research, which in October 2016 had more than 43 million members. He spotted the need for the platform when doing his PhD. Once freely registered, a user can set his or her profile and fill in their publication list, upload papers and enlist field(s) of interest, finding at the same time researchers with a matching profile. Then, it is possible to follow what academics in the field are working on,

i.e. the latest papers they are publishing, the talks they are giving or the blog posts and status updates they are writing. An important tool that Academia.edu offers is the statistic of one's downloads and page views; it also allows the researcher to know what keywords people use to search for them on Google (Giglia, 2011).

Research Gate, founded in 2008 by physicians Dr. Ijad Madisch (Boston) and Dr. Sören Hofmayer (Berlin), and computer scientist Horst Fickenscher (Berlin), is aimed at creating a working and discovering network among scientists, "Discover", "Communicate" and "Collaborate" are its main purposes (Giglia, 2011). In October 2016 it had more than 11 million members.

London-based *Mendeley*, founded in 2009 by three German PhD students (Victor Henning, Jan Reichelt and Paul Föckler), in October 2016 was used by around 2.5 million researchers worldwide to discover, share and annotate research papers (as a reference manager), and to network and collaborate with other academics (Giglia, 2011). Mendeley has two components: a desktop program and a web-based storage space, which can be used independently or synchronized (MacMillan, 2012).

The main differences among these three academic social networks can be summarized as below:

- *Academia.edu* and *ResearchGate.net* focus more on the producers of research and their networking (main function: “to be contacted”);
- While reference-sharing *Mendeley.com* sites focus on readers, helping users to share and find relevant references for their work (main function: “discover recommended papers”),

One difference still existing in October 2016 is that *Academia.edu* users can post their own papers, but *Mendeley* users can also share others' papers in their *My Library* section (Thelwall & Kousha, 2014).

Overall, it has been found that different disciplines favor different academic social networks and some authors argue that at some point there will be a “winner in the race” (van Norden, 2014). At the moment awareness among scientists of the Academic Social Networks varies, but the most well-known site tends to be Google Scholar, both among natural and social scientists, as stated by van Norden (2014).

If the Personal Social Networks have become exponentially popular among lay people by sharing personal information, snapshots on private life, CV, or even for institutions and companies aimed at their web-marketing; turning to a scholars and researchers target, the academic social networks, born in 2008, have quickly become a fundamental tool to manage, read, share, annotate and cite research papers, among tens of millions of connected users. In the era of bibliometric culture, the academic social networks – moving from the first collaborative aim of global knowledge sharing and co-producing - have also become a tool for the author's popularity. Therefore they have contributed to originate a new disciplinary field called *Altermetrics* (De Bellis, 2009, 2014), aimed at identifying new indicators for measuring their scientific impact.

This chapter first presents the literature review on the topic of Academic Social Networks, which constitutes a fairly new field of study, given their

emergence less than ten years ago. Subsequently, it focuses on the case study of the publications inspired by the theory of social representations and their presence in Academic Social Networks, exploring their characteristics (such as publication year and language) and mapping the geo-cultural contexts of the location of institutions of first authors. Follows the discussion of open networked science and bibliometric culture and possible future research directions, including further statistical analyses of existing material and switching from publications to authors as units of analysis. Finally, the conclusions concern the diffusion of the theory of social representations outside of Europe and the role of academic social networks in this process.

BACKGROUND

Academic Social Networks have become a significant part of informal scholarly communication (Thelwall & Kousha, 2014). According to Hoffman, Lutz and Meckel (2015), they provide channels for quick dissemination of research results and interaction with both peers and lay audiences, while the open access philosophy increases their appeal (Nielsen, 2012). Academic social networks address the researchers' need to ensure that their publications are accessible and visible to a wide audience (Thelwall & Kousha, 2014). They also form a part of academic identity, akin to a business card, or serve as a personal repository (Jordan, 2016).

The established services are constantly changing, hoping to improve user experience, including the design of the user interface, which has to be attractive but also simple, providing a low barrier for newcomers (Goodwin, Jeng & He, 2014). Moreover, academic social networks allow a responsiveness and informality, unlike the formal publishing process (Ovadia, 2014).

Current trends of the research on Academic Social Networks have often concentrated on users, for example Rosenzweig, Grinstein and Ofek

(2016) suggest women and authors from less economically advanced countries are more likely to utilize them. According to Williams and Woodacre (2016), the overarching outcomes of the review of research on academic social networks suggest that it falls into two primary areas: promises and perils. There has also been some research (He & Jeng, 2016), dedicated to the development of scholarly collaboration facilitated by academic social networks. On the other hand, some authors have explored the relationship between social and usage metrics, and traditional bibliometric indicators at author level (Ortega, 2015). This type of research is possible thanks to the fact that academic social networks encompass both levels, suggesting that such metrics could be used as proxies or predictors of research impact (Priem & Hemminger, 2010). Since bibliometrics (traditional techniques for measuring scholarly impact) have become well known for generating conflict and concern (Roemer & Borchardt, 2012), alternatives proposed by academic social networks appeal more attractive. Readership data also constitutes a useful supplementary measure to remedy some limitations of citation analysis across the social sciences and humanities (Mohammadi & Thelwall, 2014).

In the emerging field of research on academic social networks there have been no studies so far dedicated to a specific case of an interdisciplinary theory, comparing publications disseminated via these innovative tools. The method proposed below could be employed in other fields, taking under scrutiny a distinct school of thought.

Serge Moscovici developed the theory of social representations when assessing the process assimilation and transformation of expert knowledge on psychoanalysis among the lay people (1961/1976). According to de Rosa (1994), it can be operationalized on three different levels: a) social representations as *phenomenon* – “ways of knowing” characteristic of social reality that emerge in daily life during interpersonal communication and are directed toward comprehension

and control of the physical-social environment; b) *theory* of social representations – the collection of conceptual definitions, methodological operations and formulation of constructs that have social representations as their object; c) *meta-theory* of social representations – the collection of critical comments, ripostes and comparisons with other theoretical models which emerges from the critical debate on the theory of social representations. For a stock of the wide scientific field developed in more than 50 years since 1961, see de Rosa, (2011, 2013a) de Rosa & d’Ambrosio (2008).

ACADEMIC SOCIAL NETWORKS AND SOCIAL REPRESENTATIONS

This research is part of a wider research program led by de Rosa (2013b) dedicated to the investigation of the spread of the Theory of Social Representations (Moscovici, 1961/1976, 2000; de Rosa, 2013a), in online contexts, specifically in Academic Social Networks, taking into consideration the most important ones: Academia.edu, Research Gate and Mendeley.

This paper use data and meta-data collected by a research tool - the Grid for theoretical Meta-Analysis of Social Representation Literature - created by de Rosa in 1994 and and progressively updated depending on the development of the scientific field and the needs linked to the new forms and practices of sociology of knowledge in the *era of networked science* (Nielsen, 2012). The grid is a fundamental tool of the *SoReCom* “A.S. de Rosa” @-Library (de Rosa, 2016b). For the purpose of the research line presented in this chapter, a specific section has been added to the grid, recording each publication’s presence/absence in each of the three Academic Social Networks.

The research presented in this chapter was conducted in November 2015. Of 9414 publications analyzed, filed in the bibliographic repertories of the online *SoReCom* “A.S. de Rosa” @-Library, 6458 (69% of the total) were not found in any of

the three Academic Social Networks examined, while it has been found the presence of the remaining 2956 articles in at least one or more of them.

Concerning the distribution of the sources in the three Academic Social Networks, the most numerous contributions were found in Research Gate, followed by Mendeley and Academia. Different combinations are presented in Figure 1.

The analysis of the years of publication of literature in Social Representations is organized in decades: from 1952, the date of the article by Moscovici (1952) which can be considered a sign of the embryo-genesis of the theory of social representations (de Rosa, 2011), to the date of this empirical investigation, in November 2015. It consists of 6 decades, through which there is a progressive and increasingly widespread use of the theory of social representations:

- 1952-1961
- 1962-1971
- 1982-1981
- 1992-2001
- 2002-2011
- 2011-2015

In the graphical representation in Figure 2, there seems to be a sharp decline of production in the timeframe 2012-2015, due quite surely to the fact that the amount of time taken into account is limited to four years, and not ten as it is instead for other time periods.

Another criterion that has been adopted to analyze the sample was the language, framing the theory of Social Representations as a multi-cultural, multi-generational and multi-linguistic scientific field. As it was plausible to imagine, English ($f=1614$, 54.60%) is always the predominant language, maintaining this role in all samples analyzed - the set of 2956 items and specific items in each Academic Social Network. It seems to be the hegemonic language of the web. Moreover, English has become over the years the main vehicle of scientific communication, means of shared communication, beyond the country of publication of the native language of the scientists. Follows the order in French ($f=497$, 16.81%), the native language of the theory, born and developed in France, and Spanish ($f=406$, 13.73%) and Portuguese ($f=354$, 11.98%), incontrovertible sign that sees Latin America as the most fertilized scenario.

Figure 1. The frequencies distribution of 2956 items related to social representations in different academic social networks

Figure 2. The frequencies distribution of 2956 items related to social representations in academic social networks by decade

The classification according to the Resource Type encompasses multiple sources from which the extracted contributions that draw on the paradigm of social representations, are distinguished according to the type of publication. Various types of publications have been found in the Academic Social Networks, with the overwhelming majority of articles in scientific journals ($f=2307$, 78.04%), followed by book chapters ($f=282$, 9.54%), conference presentations ($f=224$, 7.58%) and books ($f=68$, 2.30%).

Mapping the expansion of the theory and its different spread within Academic Social Networks has always been one of the main goals of the “A.S. de Rosa” @-Library, as well as evaluating its development through various paradigmatic approaches and its dissemination in different thematic domains of applications, identifying precise geographical boundaries. Europe ($f=1856$, 62.79%) tends to be always the most dynamic area in the production and dissemination of scientific literature on Social Representations, followed by Latin America ($f=706$, 23.88%) and North America ($f=232$, 7.85%), when considering the institutions of the authors of publications on social representations that can be found in the Academic Social Networks. Latin America’s importance is in line with the overall trends of literature production

in this field, where in particular Brazilian authors are starting to replace authors from European institutions as leaders (Wachelke, Matos, Ferreira, & Costa, 2015).

In a more specific manner, this contribution examines the country of origin from which the major contributions are present in Academic Social Networks. Through the use of *Tableau software* (<http://www.tableau.com>), it was possible to create a graphical representation that would take into account the diffusion of the Theory of Social Representations in Academic Social Networks from a geographical point of view, for nations and continents. Figure 3 shows how France ($f=517$, 17.49%) occupies the undisputed first place of the greatest visibility in the Academic Social Networks of the literature inspired by the theory of social representations, followed by the United Kingdom ($f=456$, 15.43%), Brazil ($f=390$, 13.19%) and Italy ($f=198$, 6.70%).

The following continent, Latin America, presented in Figure 4 sees as the most prominent countries Brazil, Mexico and Argentina (among others with less frequencies) in this fertilised scenario.

In the remaining continents, the numbers of publications present in Academic Social Networks are progressively lower, which confirms earlier

Figure 3. The frequencies distribution of 1856 items in Europe

results of geo-mapping (de Rosa, in press, forthcoming). Figure 5 groups these “*new emerging scenarios*”.

SOLUTIONS AND RECOMMENDATIONS

Due to space limitations, it is not possible to go into detail for each of the three Academic Social Networks, where the numerical values differ for each country, but in proportion the trends tend to be the same, positioning Europe as the main continent where the authors who post their papers that use the theory of social representations, followed by Latin America and other scenarios. Certainly, international conferences play a crucial role in the dissemination of the theory (de Rosa, & d'Ambrosio, 2008), although conference presentations are not that frequently posted in the Academic Social Networks.

It is worth noting that the Academic Social Networks also play a crucial role in the debate on the evolution of the bibliometric culture in the recent decades from the scope of *information retrieval* and *science citation* (Garfield, 1955) to Webometrics (De Bellis, 2009) and beyond to *Altmetrics*, based on the transactions of users in the new scenario of the Web 2.0 and the on-growing scenario of *social networking* of especial interest to scholars now undertaking large-scale migration to online publishing and moving toward a universe of web-native communication (de Rosa, 2015a). This will not be irrelevant also for the evaluation of the science impact; in fact, some reasonable doubts about the use of social media in the research evaluation and the need to distinguish between authors' *social popularity* (based on opinion) and *scientific impact* (based on peer reviewed quality filter of scientific facts and results) have been expressed by Moed (2014).

Figure 4. The frequencies distribution of 706 items in Latin America

Figure 5. The frequencies distribution of the remaining items in North America, Oceania, Asia and Africa

The evolutionary scenario of the new bibliometric culture from *Science Citations* to *Sciento-metrics* to *Altmetrics* is widely documented in a multi-disciplinary research field which has moved from information science, informatics, statistics, mathematics, technology, communication and new media studies, but which, due to asymmetric applications in the domain of social sciences and humanities compared natural and applied sciences, has crossed epistemological issues in the history of sciences and their disciplinary policies (de Rosa, 2015a, 2016b).

FUTURE RESEARCH DIRECTIONS

While this chapter concentrated on mapping the geo-cultural trends, the limitation of presented results is the focus on descriptive statistics (e.g. frequencies). Further analyses should be carried out, including correlation of papers featured in Academic Social Networks with their bibliometrics and analysis of variance, taking into account multiple variables, such as whether the papers are empirical or theoretical, what constructs and theories they employ, etc.

A possible future research direction consists of the assessment of the “*personal profiles*” on the academic social networks of authors who publish using the theory of social representations. While the presented research is based on the presence/absence of specific publications, it is possible that not all of their authors actually have a personal profile. On the other hand, it may be interesting to trace who extensive are the personal profiles and how much information the authors are willing to include on them.

Another possible development concerns the willingness of authors to send privately or post full-text publications when prompted by other users, based on the functionalities of different Academic Social Networks that allow such exchange.

Consistently with the main goals of the overall research program aimed at the meta-theoretical analysis (de Rosa, 2013b, 2015a, 2016a), the reconstruction also in the academic social networks of the kind and evolution of inter-individual and inter-institutional co-operations is another goal of the wider meta-theoretical analysis research program. Therefore further efforts will be dedicated to the reconstruct also “within” and “by” the different academic social networks the dynamics of the knowledge epidemiology via the inter-institutional collaborations between authors belonging to institutions in different countries and continents: *who* works with *whom*, (on what) and *where*? Some tools like the analytics of the “followers” (*who is following of followed by whom*) may help to reconstruct the map of the relations among the scientists.

Moreover, a qualitative research line will be integrated with the empirical research line based on the systematic meta-theoretical analysis of the overall scientific production. It will enrich the multi-year collection of interviews already conducted by de Rosa for the main purpose of reconstructing a “*biography of the theory*” based on personal narratives of the protagonists of the theory of social representations (starting from his founder Serge Moscovici) and scholars of different generations about the relevance that this theory had in their intellectual life and the evaluation of the prospective scenario about the theory development. This qualitative extension of the study based on individual interviews will be pursued also with scientists belonging to this scientific field present in the academic social networks, orienting specific questions also aimed at revealing their attitudes towards these new environments and their motivations for using them.

Additionally, this research could be extended to other types of academic social networks aside from the three considered up to date in the So.Re.Com. “A.S. de Rosa” @-Library, which is a flex-

ible instrument, where additional variables can be included in the future.

CONCLUSION

In conclusion, it may be stated that this research has shed some more light on the diffusion of the Theory of Social Representations, the origin of a number of works and debates in social psychology, which tends to occupy a central position in the social sciences and that, as now established, meets an interest growing in different countries, in Europe and across the Atlantic. The Academic Social Networks can constitute excellent allies in spreading knowledge and - though they still relatively modestly refer to the field of Social Representations - in time it is likely to expect a progressive, comprehensive and very useful dis-

semination of scientific production using these channels, as demonstrated by literature review. The hard work done by the team of the European/International Joint Ph.D. on Social Representations and Communication Research Centre and Multimedia Lab, founded and directed by Anamaria Silvana de Rosa (2015b) has allowed generations of students and early stage researchers to work on a large sample of items relating to social representations.

The impressive number of contributions from French, English, Brazilian and Italian institutions (among many others worldwide) demonstrates that both European and non-European researchers engaged in the dissemination of the theory are succeeding in efforts to spread it using the Academic Social Networks, identifying a microcosm that mirrors a much larger universe. However, “emerging scenarios” also deserve the attention,

Figure 6. The frequencies distribution of 2956 items related to social representations in academic social networks

because it is very interesting if and how the data described in this paper (combined in Figure 6) will undergoes continuous evolution compared with the set of data gathered in different times through follow-up investigations.

KEY TERMS AND DEFINITIONS

Academia.edu: Founded in September 2008, it is an academic social network for researchers around the world to connect and share research, which currently has more than 30 million members.

Academic Social Networks: Online platforms aimed at free exchange of publications, resources and information in the realm of academia, open to students, researchers and professors. Once freely registered, a user can set his or her profile and fill in their publication list, upload papers and enlist field(s) of interest, finding at the same time researchers with a matching profile.

Altmetrics: Metrics based on social media (like blogs, Twitter, and Mendeley) which inform broader and faster measures of impact of a scientific publication, complementing traditional citation metrics.

European/International Joint PhD on Social Representations and Communication: An international joint doctorate led by the Sapienza University of Rome, dedicated to the research training in the field of social representations (<http://www.europhd.eu>).

Geo-Mapping: Technique to visualize data from different geo-cultural contexts or specific geographic locations that takes into account the cultural characteristics of inhabitants, which demonstrates the diffusion of the theory.

Mendeley: Founded in 2009 and used by around 2 million researchers worldwide to discover, share and annotate research papers (as a reference manager), and to network and collaborate with other academics.

ResearchGate: Founded in 2008, aimed at creating a working and discovering network among scientists, “Discover”, “Communicate” and “Collaborate” are its main purposes, in January 2016 it had more than 8 million members.

So.Re.Com. “A.S. de Rosa” @-Library: A multi-purpose web-platform for integrating scientific documentation, networking and training in the field of Social Representations and Communication (So.Re.Com.) (de Rosa, 2016b).

Social Representations: A construct developed by Serge Moscovici (1961/1976), which – according to de Rosa (1994) - can be operationalized as “ways of knowing” characteristic of social reality that emerge in daily life during interpersonal communication and are directed toward comprehension and control of the physical-social environment.

The NetLab Network

S

Dimitrina Dimitrova*York University, Canada***Barry Wellman***NetLab Network, Canada*

INTRODUCTION

The NetLab Network (“NetLab”) is an interdisciplinary scholarly network studying the intersection of social networks, communication networks, information networks, and computer networks. NetLab gets its identity and zeitgeist from its distinctive subject matter, multi-disciplinary nature, and the way in which it functions as a social network.

As a network in its own right, NetLab comprises shifting teams, spatially dispersed relationships, and permeable boundaries. Its members have come from many disciplines: Communication Science, Computer Science, Geography, Information Science, Management Science, and Sociology. NetLab has been inclusive in academic status, including faculty, graduate, undergraduate, and high school students. Although centered at Toronto, Canada, NetLabbers are elsewhere in Canada, as well as Australia, Chile, China, England, Israel, Italy, Japan, Norway, Singapore, and the United States. Connecting them is a shared sensibility of interpreting behavior from a social network perspective rather than seeing the world as composed of bounded groups, tree-like hierarchies, or aggregates of disconnected individuals.

Not only ideas connect the network. NetLab is an informal network of collaborators - faculty and students - that function as a community of practice: a self-selected, self-organizing, informal group of collaborators who solve problems together and learn from each other. In addition to congruent intellectual perspectives, frequent communication and a culture of inclusiveness and

mutual supportiveness also connect NetLabbers. With its paramount interest in social networks, as well as its collaborative focus, interdisciplinary nature, remote team members, and partnerships with government and industry, NetLab exemplifies key trends in research (Wellman, et al, 2016). It is important not only for what it does but for also how it achieves it.

This chapter summarizes and updates an earlier description published in the *Encyclopedia of Cyber Behavior*. As the space allotted for this chapter is less than half of the original chapter, we emphasize recent research and refer readers to the earlier version for fuller discussions, citations and references (Dimitrova & Wellman, 2012).

GUIDING PRINCIPLES

NetLab research has been informed by a set of guiding principles:

1. *The world is composed of networks, not groups.* People function more as individuals connected via partial memberships in multiple networks and less as people embedded in tightly-bounded, densely-knit, settled groups.
2. Many people meet their social, emotional, and economic needs by tapping into multiple, loosely knit networks of diverse associates rather than relying on tight connections to a relatively small number of core associates.
3. The social structures people are in largely determine the operation of two-person re-

DOI: 10.4018/978-1-5225-2255-3.ch612

- lationships: it is sociology, not psychology. Ties are usually asymmetrically reciprocal, differing in content and intensity.
4. Ties link network members indirectly as well as directly.
 5. Asymmetric ties and complex networks differentially distribute scarce resources.
 6. Information and communication technologies (ICTs) are usually extensions and enhancers of ongoing relationships. Few people have most of their ties in segregated virtual worlds.
 7. Households have become more networked, with ICTs keeping mobile spouses and their children in contact.
 8. At work, less-formal, fluctuating and specialized peer relationships are common, and the benefits of boss/subordinate hierarchical relationships are less obvious. The organization of work has become more spatially distributed, with ICTs connecting people, and appreciable numbers working at home full or part-time.
 9. As the dividing line between work and home has weakened, so has the more general boundary between the private and public spheres of life. In the less hierarchical and less bounded networked environment where expertise is more in dispute than in the past and where relationships are more tenuous, there is more uncertainty about whom and what information sources to trust.
 10. Social movements arise out of both existing social networks and more organized groups; they rarely are disconnected bunches of alienated individuals.

BACKGROUND

Although social networking services such as Facebook, LinkedIn, and Twitter have highlighted the connection between social networks and technology, NetLabbers have looked at social

networks – spatially distributed and sparsely knit – for decades. The International Network for Social Network Analysis was founded at the University of Toronto in 1977, and many local scholars have used a common network analytic approach in a variety of substantive areas and topics. Some focused on large-scale structures and their implications while others focused on interpersonal relations.

In the early 2000s, a cohesive set of scholars started examining how the internet fits into community and family life, friendships, civic involvement, and health practices. The network jelled, linked not only by overlapping research interests but also by a propensity to collaborate and help each other. They had an understanding of their overlapping intellectual pursuits and the connections among them, but they lacked a name and a distinct identity. Creating NetLab formalized existing practices of collaboration and gave an identity to an already well-functioning network of faculty and students.

The creation of NetLab – as a brand independent of any scholarly discipline – also facilitated the involvement of scholars from a variety of disciplines. Then and now, the boundaries of the network have been flexible: Faculty members are engaged to a different degree depending on the mix of projects they have at a particular moment in time. Students come in and out, graduate from university, or finish internships. Members move away or change interests. Yet the network remains: Former students come back for a visit or engage as collaborators; network members collaborate and ask for help with relevant references, a survey protocol, or an ethics submission.

Branding the network as “NetLab” provided a useful identity. It gave visibility to the University of Toronto among the global network of social network scholars; it provided an easy way for other scholars to connect with network analysts. It provided a quasi-formal identity to scholars, the general public, the media, and government bodies, NGOs, and corporations interested in the

social network approach. Former students at NetLab have graduated to launch their own research programs that build on and expand on NetLab's research concerns. Some continue their interests in social capital or the way media is involved in social networks.

All this happened with a loosely bounded and fuzzily defined informal network. So NetLab became the name and the brand. It reflects the combination of serious scholarship and joyous collaboration. It reflects NetLab's openness to studying all sorts of networks: social, communication, information, and computer. No longer based at the University of Toronto, it is today "The NetLab Network," but informally still "NetLab".

COMPUTER NETWORKS MEET SOCIAL NETWORKS

The essence of NetLab is *social* networks, not *computer* networks. But, starting in 1990, a series of collaborative projects focused on the ways people used ICTs for work and community. Toronto computer scientists in the Cavecat and Telepresence projects were attracted to NetLab's focus on work and leisure communities that transcended the traditional local proximities of work groups and neighborhoods. Several projects on the remote collaboration at work highlighted the importance of social context. For instance, a study of home-based teleworkers found that work tasks and supervision shaped their patterns of mediated and face-to-face communication. Similarly, the ways in which employees of a distributed organization used a pioneering desktop video conferencing system reflected their need of autonomy.

Significant efforts concentrated on how the emerging internet affected scholarly networks and community. Digital divide studies addressed an early concern: which kinds of people were actively using the internet? Scholarly network studies discovered that friendship was as important for the connectivity of white-collar employees as their collaborative work, and that weak ties

among scholars were especially important for increasing the pool of available advice givers. The "Netville" community study showed that rather than destroying neighboring, the internet increased both local and long distance connectivity. These studies also had the effect of shifting research away from experimental groups and phenomena such as telework or video conferencing to looking at how ordinary people incorporated ICTs into their lives.

NetLab's projects in the early 2000s solidified its theoretical orientation, substantive focus, methodologies, and interdisciplinary orientation. Among the key ideas was the understanding that computer networks link people as well as machines. In other words, computer networks are social networks. At a time when the analysis of online relations tended to focus on ties between two people, NetLabbers emphasized the embeddedness of such ties in networks connecting people in-person as well as online. This interpretation had major implications for the study of ICTs: it meant that NetLabbers could fruitfully use the same intellectual apparatus for studying the internet that they had used to study work, community and households. This background enabled NetLab researchers to wade into major debates about the significance and implications of internet and mobile technologies on interpersonal relations, communities and organizations. Instead of armchair theorizing, they were armed with a broad theoretical approach, systematic methods, and a knowledge base of research lore. A continuing research thread in findings is: "the more, the more, the more." That is, the more social ties people have, the more they use digital media, and the more social support they exchange.

The central presence of social scientists in NetLab provided an emphasis on social context and linked its research to broad societal trends and the history of science and technology. This allowed the group to avoid the common pitfalls of early research on ICTs. Instead of implicit technological determinism – where computerization directly determined behavior -- NetLab researchers saw technology as providing social

affordances, i.e. opportunities and constraints for social relations. The broader social context of NetLab's studies allows scholars to question ahistorical assumptions about ICTs. Rather than assuming that ICTs have no precedent in the past, NetLabbers have shown how debates about whether ICTs enhance or diminish community are continuations of centuries-old debates about the impact of the industrial-bureaucratic revolution on community. Instead of pedantically arguing about the theoretical effects of ICTs, NetLabbers have collected systematic evidence from surveys, in-depth interviews, and ethnographies. Instead of adopting parochial views that ICTs could be understood in isolation from face-to-face and phone communication interaction, and that only online phenomena were relevant for understanding the internet, NetLab researchers looked for the interplay between communication online and offline.

Such an approach has coupled with an appreciation of the social affordances of a series of successively developed technologies. NetLab research started with email and early collaborative technologies. Later studies turned to digital media, both interpersonal and social (e.g., Takhteyev, et al., 2012; Gruzdz, et al., 2012). Two key phenomena discovered in the research were *local virtualities* – where physically proximate people communicate online and *virtual localities* – where physically dispersed networks form communities online.

Researchers at NetLab have situated analyses in the context of historical trends and broader social phenomena. This leads them away from simplified utopian/dystopian interpretations of the affordances of ICTs. NetLabbers have shown that digital media have become incorporated in everyday life. They not only give people speed in data-heavy exchanges but also enable them to stay always connected and to make their communication personalized and portable. For example, NetLab researchers demonstrated that the use of ICTs could support both strong and weak ties, and that ICTs rarely replaced face-to-face interactions but were used instead to communicate in-between

face-to-face contacts (Wang & Wellman, 2010; Rainie & Wellman, 2012). Nor have ICTs decreased the importance of proximity or precluded travel: Rather, they have been incorporated in the variety of tools people use to maintain their networks (Dimitrova, et al., 2015). Online connectivity may even increase face-to-face interactions and community engagement. People stay both locally embedded and globally connected, and have more close relationships, support, trust in others, and civic engagement.

Anabel Quan-Haase's book, *Technology and Society: Social Networks, Work, and Inequality* (2015), presents these and other findings in depth, examining the places where technology and society intersect; connecting technology to issues of social networks, communication, work, power, and inequality. Focusing on Canadian society, she provides an overview of how ICTs are changing peoples' perceptions of themselves and their relationships.

COMMUNITY AND HOUSEHOLD STUDIES

“Connected Lives” and “Networked Individuals”

To understand the networked nature of community, NetLabbers have studied a residential area of Toronto – East York – via surveys and in-depth interviews in four waves: 1969, 1979, 2004-2005, with the latest study starting in 2012. The most recent wave focuses on how the internet fits in with friendship, community, social capital, domestic relationships and civic involvement. This research has found that people happily integrate the internet into their personal networks: at home, at work, and with their families. There is strong evidence that the internet is promoting community, and that it is not a separate, alienating world. Communities are no longer bounded groups but are partially connected networks whose ties reach

out into different spheres, linking people near and far. A culture of frequent connections has permeated families, keeping in touch during the day via email, texting and mobile phones. Many East Yorkers use digital media to work at home, either part-time or full-time (Kennedy, et al. 2011; Rainie & Wellman, 2012; Mathias, 2013).

This research is congruent with a national U.S. survey showing that the number of close friendships had increased in the United States between 2002 and 2007. Belying fears that internet use had caused the atrophying of relationships, the analysis revealed that not only do heavy internet users have more friends than light or non-users, but also that heavy users have experienced the greatest growth in the number of friends during that time period (Wang & Wellman, 2010).

Elsewhere in the world, NetLab's Japanese research in the Yamanashi prefecture depicted how young adults used web-enabled phones instead of personal computers almost a decade earlier than their North American counterparts. The findings indicate a division of ICT use in Japan, with smartphone messages used to contact socially-close supportive relationships and email used to expand and diversify messages (Miyata, et al., 2008).

NetLab's East Asian research suggests that "networked individualism" is more than a Western world phenomenon. The researchers find similar situations in Japan, China, Korea, and Singapore: multiple partial communities, using digital media, trains and planes to connect over long distances. Key differences between North American and East Asian networked individuals are the heightened importance of kinship ties and age seniority (Chua, 2011; Chua & Wellman, 2015, 2016).

Another longstanding divide has been the elderly who are less likely to use ICTs. Neves, et al. (2013) in Lisbon and Quan-Haase, et al. (2016, 2017) in East York suggest this gap is lessening. The widespread need for ICTs means the young are teaching the old, and the formerly young are growing older and bringing digital literacy with them.

SOCIAL CAPITAL

Many NetLab members are interested in interpersonal social capital: network ties that may be mobilized as resources. Keith Hampton, et al. (2016) show how ICTs provide heightened awareness of life events in the lives of both close and more distant acquaintances. Awareness of undesirable events can lead to stress. Women tend to report greater stress than men and from a wider range of events. Hampton (2016) argues that ICTs affordances of persistent contact and pervasive awareness are ushering in changes to the structure of community that may revive the constraints and opportunities of premodern communities. Through the ambient, lean, asynchronous nature of ICTs, awareness supplements surveillance with the informal watchfulness typified in preindustrial community.

Such results fit with experimental work focusing on how individuals use ICTs to maintain and build their personal networks in their daily lives. Thus, smartphones both enable or hinder the transfer of information and support within social networks. For example, smartphones can mitigate tele-cocooning by stimulating communication between weak ties (Boase & Ling, 2013; Kobayashi and Boase, 2015). At the same time, ICTs are associated with an increased use of public space, with people being more connected than a generation ago (Hampton, et al., 2015).

Other NetLab research looks at networked individuals using their ties for advancement. Indigenous entrepreneurs use various forms of social and cultural capital in their networks to mobilize resources (Côté, 2013). Marin (2012) reveals how information holders choose to share or withhold job information from network members who they believe to be suitable for known job openings. They are more likely to share job information with strong ties and when job openings are located in closed labor markets.

Networked information pervades health awareness and care. Gruzdt & Haythornthwaite (2013) described a community in which both formal

health providers and informal advisors used ICTs to discuss health topics. By contrast, those who seek alternative health care, such as naturopathy, rely on ties with friends and relatives for advice and connections and often do not tell their physicians (Wellman & Kelner, 2015).

NETWORKED STRUCTURES

Networked Scholars

The NetLab's Network Assessment and Validation for Effective Leadership (NAVEL) team spent more than five years participating in and simultaneously studying a large multidisciplinary and multi-institutional Canadian research network, GRAND. The project examined how scholars from computer science, social science, health sciences, and the humanities collaborated over five years. The study sheds light on research collaboration and demonstrates how networked organizations actually operate (Dimitrova, et al., 2015a, 2015b). While networked organizations are especially common in research, most discussions are more cheerleading and anecdote than analytic research.

NAVEL's research focused on how new digital technologies and network structures affect team performance and innovation. Researchers found a network whose uneven connectivity was associated with formal organizational position, academic seniority, and disciplinary background. Leading researchers--usually older and more senior--had twice the ties of their junior collaborators; computer scientists were more connected than academics in humanities and social sciences, and cross-disciplinary collaboration linked functionally close discipline (Dimitrova, et al. 2013; 2015c). To connect with each other, GRAND researchers relied mostly on email and in-person chats. Despite ICTs' facilitating of long-distance ties, researchers tended to connect and work with nearby scholars (Hayat & Mo, 2015; Wellman, et al., 2016).

As a longitudinal study, NAVEL offers insights on the evolution of research networks (Dimitrova, et al. 2015c; Hayat & Mo, 2015). Cross-disciplinarity, geographic dispersal, and institutional diversity fostered the creation of more volatile and easily dissolved ties. While networks did not substantially change, ties were frequently added and dropped—especially ties across disciplines, institutions, and locations. The researchers liked the intellectual challenges of cross-disciplinary collaboration and actively created new ties, but did not always sustain them. Both the scholars' social status in GRAND and the structural holes in their networks shaped their exchanges of advice and their collaborations. We caution that because such multidisciplinary, multilevel networks are more complex, they can be slower to produce traditional academic outputs and they cannot be evaluated only by traditional measures.

NAVEL's results echo the findings of two earlier NetLab studies of collaborative research networks of academic, government, and private sector participants that highlighted the continuing relevance of disciplinary boundaries (Dimitrova & Koku, 2009). Nor are such networking dynamics confined to the scientists. Another NetLab study of digital humanities suggested that in the humanities, large-scale collaborative networks had greater network density and integration, without necessarily increasing the level of in-depth collaboration typically found in the sciences (Quan-Haase, et al. 2015).

Networked Learning

Just as communities used to be (mostly) bound up in neighborhoods, formal education used to be bound up in school classrooms. Yet digital media and networked individualism are enabling school-agers and lifelong learners to obtain knowledge from a variety of sources, from Facebook and Google to massively open online courses. Haythornthwaite, et al. (2016) are leading the explorations of this area.

Networked Influence

In a networked society, social influence has become networked influence: it occurs in social networks and propagates through online communication networks (Gruzd & Wellman, forthcoming 2016). Working from this premise, Gruzd's coordinate Social Media Lab finds that while there are some pockets of political polarization on the Twitter social media platform, it also facilitates open, cross-party, and cross-ideological discourse (Gruzd, et al., 2016; Gruzd & Wellman 2016; see also Gruzd, et al., 2012; Miyata, et al., 2015).

Transnational Entrepreneurs

The Information Technologies and Transnational Entrepreneurship Project studied how ICTs and planes allow global connectivity. The "net and jet" helped Chinese immigrants to stay connected in North America and in their homeland, relying on glocalized networks and the internet to engage in transnational entrepreneurship (Chen & Wellman, 2009). Chen currently collaborates with University of Texas colleagues analyzing the relation of social media, social networks, and global media flows (Chen & Reese, 2015).

DEVELOPING NETWORK METHODS

Advanced methods have been a continuing thread in studying networked relationships. Bonnie Erickson pioneered the "position generator" to measure the resources people are people linked to and how differences in network contacts with different jobs have life consequences (Lin & Erickson, 2008).

Anatoliy Gruzd is developing automated text mining and visualization tools for uncovering and representing online social networks (Gruzd & Wellman, 2014). He and the associates at his Social Media Lab have put these tools to good use studying how academics, professionals, and ordinary people use social media and how social media are implicated in knowledge exchange,

collaboration, and social influence processes. The continuing development of tools and methods enables and, in turn, is reinforced by the expanding research agenda of the Social Media Lab.

Concomitantly, Boase and Ling (2013) have incorporated digital trace data into their project designs, merging it with more traditional survey and interview data. Marin and Hampton (2007) have shown ways of simplify data collection using name generators while ensuring reliability. Bernie Hogan is developing novel data collection techniques that blend qualitative and quantitative approaches to understand how people perceive and act on social networks. He developed participant-aided sociograms with the Connected Lives team and later turned to online audit studies (Hogan & Berry, 2011). He has also blended this empirical work with a theoretical expansion of the social affordances concept (Hogan & Wellman, 2014). Hogan (2015) argues that instead of alphabetical or chronological order, information providers should use the logic of machine learning with data-as-graphs to train multidimensional systems.

The complex reality of the scholarly network studied by NAVEL enabled the development of multilevel, multimember modeling and sequencing analyses. These are useful tools for longitudinal studies of networked organizations and networked workers who are partial members of multiple teams (Mo, 2012; Mo & Wellman, 2016).

CONCLUSION

As a community of practice, the NetLab Network has had two main achievements. First, its researchers have made substantive contributions to the issues at the intersection of social networks, communication and computer networks. The accumulation of tacit and explicit interdisciplinary knowledge at the NetLab Network not only lends depth and sophistication to research results; it has reached a stage which enables the development of theory.

Second, NetLab has demonstrated that its model of scholarly collaboration works. Its members practice, analyze, and preach being networked. Their collaborative relationships span both disciplines and academic status and have connected a diverse network of scholars. Their informal, but serious collaboration enables bouncing off ideas and has proven especially conducive to novelty and creativity.

A recent book – *Networked: The New Social Operating System* (Rainie & Wellman, 2012) -- is an exposition of much of NetLab's intellectual capital and research lore. It brings together different strands of the work done by NetLabbers for the past four decades and adds other relevant contributions about social networks, interpersonal relations, the family, work, information, and creativity. The key thread running through the book is the "Triple Revolution": the turn to social networks, the internet and mobile connectivity and the way these revolutions affect everyday life. The authors contend that the Triple Revolution is building social relationships based on "networked individualism", a paradigm shift in the way people are connected: from relatively homogenous, broadly-embracing, densely-knit, and tightly-bounded groups to more heterogeneous, specialized, sparsely-knit, and loosely-bounded social networks. These developments serve as both a summary of research knowledge and a guide for future research. Above all, they demonstrate that the shared perspective binding the NetLab network together is not frozen in time but reflects the intellectual growth of its members. NetLab is well-positioned to make its next steps.

KEY TERMS AND DEFINITIONS

Community: Tightly bound groups of people with shared interests and values, common identity, and a sense of belonging. Current approaches treat communities as delineated by interaction and commitment (e.g. virtual communities) rather than by location (e.g. neighbourhoods).

Networked Individuals: Connected individuals embedded in multiple partial networks instead of than being members of dense tightly bound groups.

Networked Organizations: Organizations where extensive use of computer networks and mobile technology is coupled with changes in group dynamics, communication, and authority.

Networked Workers: Rather than working in a single work group or independently from others, networked workers work in multiple, often distant, teams and projects.

Scholarly Networks: The networks of academics and researchers linked by one or more relations; such networks are increasingly becoming formalized, multi-disciplinary, geographically distributed, and reliant on technology.

Social Network Analysis (SNA): An interdisciplinary perspective which focuses on the patterns of relations among social actors and interprets these patterns as social structure.

Social Networks: A set of social actors - be they individuals, groups, organizations, or countries - and the relations among them.

Triple Revolution: Social transformation comprised of: (a) the change in social networks from people being embedded in tightly bound groups to people being embedded in multiple partial network (aka *networked individualism*); (b) proliferation of internet technology; and (c) spread of mobile technologies.

Online Dating/Dating Apps

INTRODUCTION

Over the past several years, online dating services are increasingly becoming popular venues for finding romantic relationships. In 2012, Match.com reported that one in six marriages started online (Ramirez, Sumner, Fleuriet & Cole, 2015). In 2013, the online mating services brought \$2.1 billion (Ginsberg, 2015) whereas compared to ten years ago, in 2004, the dating industry revenue was only \$473 million. Nowadays, there are many online dating sites such as Match.com, eHarmony, and PerfectMatch.com, with over 50 million users combined (Consumer Rankings., 2012), and the online dating business keeps growing (Visual Economics Credit Loan blog, 2015). Online dating refers to web sites and apps that facilitate romantic relationships' initiation by offering users (1) access to the profiles of potential romantic candidates, (2) a communication channel to initiate contact, and (3) a romantic compatibility matching-algorithm to be paired for potential romantic initiation (see Finkel, Eastwick, Karney, Reis & Sprecher, 2012). Indeed, most online dating platforms are similarly structured (Rosen, Cheever, Cummings & Felt, 2008), in general: users post a photograph and answer questions in regards to personal information and other relevant demographics; however, there is considerable variance among online dating forums with regard to users' level of involvement, interaction, and self-disclosure.

Despite the array of online dating sites and apps, a new online dating app entered to the online dating market, and it is taking over the entire online love business: Tinder. The new app

just entered to the market in 2012, and, two years later, it reached approximately 30 million users, almost a third of the total online dating population (e.g., 96 million users) (Forbes, November 2014). Thus, the popularity of the app has rapidly grown. Tinder app innovates the usual online dating service explained above, by providing users a seemingly endless selection of photos of potential mates without the need to answer questionnaires or forms (Bertoni, 2014a); then, the algorithm of the app links users' contacts from Facebook profiles to provide photographs of potential romantic candidates. After solely looking at photos of potential mates, users swipe right if they like a person and, by the contrary, swipe left if not (Bertoni, 2014a); finally, if both parties like each other, the platform provides a parallel interface to send messages to each other to decide whether or not to meet in person and exchange personal contact information.

Besides the successfulness of online dating market, the online dating service has always been severely criticized for its 'overemphasis' on physical appearance. However, disregarding the communication context (i.e., Face-to-Face and Online), physical appearance is the initiator for communication behaviors in most of the cases. The online dating success trend has been widely explained by the new media pervasiveness argument or the idea that this service is prosperous 'only' or 'mostly' because the access to personal computers and smartphone is wide spread, then focusing only on related phenomena such as self-presentation, self-disclosure, and/or social anxiety. If new media pervasiveness explains this new

social trend, why did commercial video-dating not become so popular during the 90s when the access to video cameras was also pervasive in the U.S.? Little attention has been directed to how online dating mirrors human perception of first impression while forming interpersonal relationships.

Therefore, the present chapter understand the role of human perception of physical appearance during first impression formation which may better tune with Tinder' interface; in other words, Tinder feels more natural to users compared to other dating apps, swipe to left or to the right feels better than 'browsing' profiles; in addition to the pervasiveness argument of new media and apps, this chapter explains Tinder' increasing popularity seems to match to interface architecture as well. Consequently, the concept of technological affordance tuning will be discussed to explain the success on online dating in addition to new media pervasiveness argument; however, the idea of affordance tuning is not widely discussed in the CMC research on online dating, and this concept is the main contribution from this chapter.

BACKGROUND

The online dating technology has been around since 1970, but the rapid rate of development of cheap, fast, reliable, and user personal computers with Internet made online dating technology to evolve from being just an online interface for personal romantic advertisement (see Byrne, Ervin & Lamberth, 1970), then to become an algorithm-based matching system (i.e., e-Harmony.com or Match.com) to finally a combination of both; with the inclusion of smartphone-based dating applications and GPS technology (i.e. Blendr or Skout), the new version of this CMC technology also became into satellite dating (Quiroz 2013). Nowadays, online dating users cannot only browse romantic candidate profiles, but also know where they are given information to decide whether or not meet them in person. But, if online dating success is explained by the argument of new media

pervasiveness solely, then why did commercial video-dating not enjoy similar popularity during the 1990s when the access to video cameras was also pervasive in the U.S.?

Then a new app entered to the market in 2012: Tinder. In only two years, in 2014, Tinder reached approximately 30 million users who have used this app to find a partner making, more than 15 million matches daily; then, users are checking out about a 1.2 billion profiles -14.000 per second- (Bertoni, 2014). While the entire U.S. dating business is worth somewhere between 5 and 6 billion dollars (Forbes, 2014), just Tinder is worth somewhere between \$.1 billion and \$.1.5 billion, and some big bank analysts said that Tinder could even top \$. 5.5 billion in few years, which is almost the entire online market soon (Forbes, 2014). The app is very popular and is one of the top producing online dating apps.

This chapter argues online dating popularity responds more to how technology closely mirrors actual human interaction in the early stages of forming a romantic relationship than other (and earlier) dating services venues; furthermore: why did Tinder get that level of popularity in only 4 years, whereas other online dating sites have been around for more than a decade without obtaining the same users' preference? There exists a constant tension between tasks and technologies in interface design; Gaver (1991) accurately explains that a design based on only technology innovations is functionally awkward, and, by the contrary, a design just based on users' needs may lead to overlook technological innovations; indeed, the main purpose for artifact interface design should be to create a CMC architecture which reflects an interaction between human sensory systems and CMC affordances. Consequently, in order to answer the main queries of this chapter, non-verbal research on physical attractiveness and first impression formation with the concept of affordance tuning along the way will be discussed to explain online dating increasing engagement across the world, an idea which has been ruled out by scholarly research.

MAIN FOCUS OF THE ARTICLE

Issues, Controversies, Problems

Many individuals have assumed new, and even counter, identities in their pursuit for online romantic relationships (Alapack, Blichfeldt, & Elden, 2005). The Internet and CMC (Computer-Mediated Communication) have become suitable forms of communication between individuals looking for controlled forms of relational engagement (Hardey, 2004); the online dating phenomenon reflects the same motivation that seeks romantic outcomes (Whitty, 2008; Heino, et al., 2010; Kang & Hoffman, 2011; Finkel, Eastwick, Karney, Reis, & Sprecher, 2012); Ramirez, Summer, Fleuriet, & Cole, 2015) such as pursuing to attain a long-term relationship commitment (Mahfouz, Philaretou & Theocharaous, 2008).

However, the observable human behaviors associated with online dating have traditionally been isolated to textual inferences. For example, online dating has been research on the basis of Walther's (1996) 'Hyperpersonal' model which aims to understand how users take and advantage from CMC affordances to overcome the absence of nonverbal cues (Walther, 1996, 2007). Thus, in CMC, users create and exchange messages in physical isolation from receiver, masking involuntary cues which make users perform overattributions based on stereotypical impressions of their partners without qualifying the spontaneity of such impressions. In other words, as senders, users do not show their "*their natural physical features and non-deliberate actions into the receiver's realm of perception*" (Walther, 2007, p. 2541, Italics added); then, it can be inferred that online dating fits better for users' dating goals in terms of having more control on first impression formation.

For many individuals, the thought of going online to pursue a romantic relationship seems different and unorthodox (Anderson, 2005). In a study attempting to measure attitudes related to Internet romance, numerous results indicated var-

ied levels of romantic satisfaction. For individuals with high levels of *Internet affinity*, or the desire to interact via the Internet, their perceptions of romantic relationships were seen as positive and enduring (Anderson, 2005). Research suggests that there is a relationship between levels of perceived realism and individual perceptions of online romantic relationships. Surprisingly, the results did not support a positive relationship between levels of perceived realism and online romantic relationships. Anderson (2004) discovered that there would be a positive relationship between amount of time (hours per week) on the Internet and perceptions of online romantic relationships. Anderson (2004) found that a high degree of Internet use was instrumental in establishing positive perceptions of online romantic relationships. Anderson (2004) noted that individuals must adjust their behaviors to the new environment created by online dating. Further, individuals engaging with online relationships must adopt new forms of nonverbal behaviors in order to offset the absence of traditionally implemented offline cues.

Just as with face to face relationships, online relationships are governed by certain codes and standards (Hardy, 2004). *Netiquette* asserts itself as the ruling body for all forms of romantic online exchange (Hardy, 2004). Research dedicated to online romances has reported that online dating services allow for high volumes of information to be transferred between sender and receiver (Hardy, 2004). Unlike print forms of dating services such as the use of newspaper classifieds, Internet services allow individuals to disseminate a plethora of biological facts at a faster rate (Hardy, 2004).

One of the greatest forms of romantic information dissemination is based on nonverbal elements. According to Hardy (2004), the posting of one's photograph onto the web is a very personal decision. For some the posting of a photograph takes away from the *otherworld* experience they are trying to manifest through online interaction. Individuals that choose to eliminate their photo seek to maintain a sense of relationship based on emotional and intellectual criterion and not physi-

cal characteristics (Hardy, 2004). For others, the exchanging of photographs act as a mechanism for the reduction of feelings related to ambiguity and uncertainty (Hardy, 2004). The practice of sending a picture electronically allows both parties to construct a more vivid, while still nonverbal representation of the other person. Further, by sending a picture, both parties are better prepared for face to face interaction (Hardy, 2004).

Social relationships start from first impression formation (Richmond, McCroskey & Hickson, 2007), and, simultaneously, first impression is formed through physical attractiveness assessment. Consequently, dating is not the exception for physical attractiveness as the basis for first impression formation (see Richmond, et al., 2007; Tidwell, Eastwick & Finkel, 2012); Eastwick & Hunt, 2014). Indeed, nonverbal research in interpersonal relationships suggests that physical attractiveness is what determines initial communication approach (Richmond, et. al., 2007). But, attractiveness assessment is individually performed and visually driven, it is in the eye of the beholder (Richmond, et. al., 2007); for example, in Eastwick and Hunt (2014) measured romantic acquaintanceship in three different times in three separated studies with a total of 309 undergraduate participants, the results suggested that the romantic evaluation of potential mates is more unique to a person that consensual over time.

Physical attractiveness primarily sets off first dates in online settings as well (see Walther, 2007; Kang & Hoffman, 2011; Finkel et. al., 2012; Ramirez, et al., 2015). The problem arises when first impression formation is mediated by computer technology because it extrapolates and enhances attractiveness in a hyperbolic way: during the receiving stage in the communication system, users perform an overreliance (idealize) on others' traits because they only have access to the available pictures and textual information and messages which prompts minimal similarity; on the other hand, in the sender communication stage, individuals selectively self-present in a controlled and social desirable fashion; while as a

communication channel, CMC facilitates editing, discretion, and convenience to form impressions (see Walther, 1996, 2007). As a matter of fact, physical attractiveness is found to be the most valued aspect in online dating (see for a review Whitty, 2008; Rosen, Cheever, Cummings, & Felt, 2008; Turner & Hunt, 2014); for example, Ramirez, et. al., (2015) found that perceptions of higher levels of intimacy, informality, composure, and social orientation were positively predicted by the number of photographs that users had on their profiles. Therefore, attractiveness is the strongest predictor for online relationship initiation (Whitty, 2008; Walther, 2008; Finkel, et al., 2012; Ramirez, et al, 2015). Consequently, the important role of physical attractiveness for dating explains the central role of personal pictures in online dating interface architecture, but this is an idea not widely discussed in the scholarly literature.

CMC offers a virtual environment in which the physical isolation prompts anonymity and makes users experience more disinhibition; for example Lapidot-Lefter and Barak (2012) examined the effect of anonymity/non-anonymity, visibility/invisibility, and eye contact/absence of eye contact in an experimental design with 142 participants (71 men and 71 women) from ages 18 to 34 years during shorts debates through CMC; thus, a factorial experimental design was conducted, and the results suggest that lack of eye contact was the primary contributor to online disinhibition effects. As a consequence from acquiring control of the new language system through CMC, individuals are able to openly express their feelings and emotions with one another. According to Alapack et al. (2005), the courtship behaviors created by the evolving language system tend to limit romantic feelings such as awkwardness and conflict. Moreover, the use of tactical punctuations during romantic interludes causes the online environment to become strikingly similar to that of the real world (Alapack et al., 2005).

Besides the currently broad access to personal computer and smartphones that is also a factor to the increasing popularity of online dating, it

is worth to consider that any technology device become popular when its use is more close to naturalness (Xie & Newhagen, 2012); in other words, individuals tend to use more the devices that are feel natural to perform a given task. The concept of affordances refer to the process in which individuals perceive the objects in their environment in terms of its potential for action, without significant intermediate stages that require memory or inferences. For example, a chair is perceived in terms of its 'seatability'; hence, people perceive the affordance of 'seatability' (Gaver, 1991). Accordingly to Gaver's example, an affordance is determined in terms of the attributes of both actor and object; subsequently, there should be perceptual information for an existent affordance. Ergo, affordances are basically determined by the physical properties, shape and scale of artefacts that are more or less easy to be perceived by specific human perception processes, and first impression formation process seems to fit better with online dating.

Online dating affordances give users a broad range of choices to 'control' self-presentation in terms of physical attractiveness and personal information that permits impression management behavior. Hence, online dating interface architecture seems to line up in parallel to Gaver's (1991) requisites of affordance because for interface design the following postulates should be considered: 1) the artifact physical attributes should be compatible with those of the actor, and, in online dating, the visual perception and assessment of physical attractiveness is paired with the central role of personal pictures in this platform; 2) the information of the artifact' attributes are available in a manner compatible with a perceptual system of the actor, and this CMC technology is a visually driven device to perform romantic assessment; and 3) the attributes and the action should be culturally and personally relevant, and, in online dating, the profiles are individually accessed, but culturally valued, as physical appearance evaluation is performed. The affordance tuning for technology design seems to be more appropriate

in Tinder in which users do not need to fill in long questionnaires, and simply go visually during attractiveness assessment to then asking questions to candidates, as it happens during FtF settings.

SOLUTIONS AND RECOMMENDATIONS

As online romantic conversations begin to evolve and take shape, scholars must continue to observe and examine online relational phenomena through the use of online dating apps which have stronger effects on individuals due to its perceived 'naturalness' for its 'proximity'. Through CMC affordances such as the use of emoticons and other tactical punctuations, nonverbal communication plays a crucial role in the development of Internet-based courtship behaviors and romantic online relationships. Online dating and online apps have changed the way that people pursue romantic relationships; it is not only important for scholarly research to understand how users exploit CMC affordances to overcome its limitations as Walther's model proposes, but also it is paramount to include the analysis of how those affordances specifically tune to human perception process making in it more or less 'popular', or more or less 'interactive' which is also part of the market successfulness of any technology, as it can be inferred while trying to answer the question about why video dating did not become as successful as online dating did.

FUTURE RESEARCH DIRECTIONS

Future research should look at how closely online and offline courtship behaviors overlap each other by introducing the affordance tuning conceptualization and nonverbal research. In addition, future research should investigate the communication behaviors that individuals use on online apps compared to face-to-face interactions; for example, Hunt, Eastwick & Finkel (2015) compared

the length of acquaintanceship [first impression formation] of 167 couples taken from previous longitudinal studies, and they found a negative interaction between physical attractiveness and the time couples got to know each other (i.e. up to 9 months). In other words, the longer individuals had known each other, the less probability for choosing a mate by the attractiveness criterion, but most likely by psychological similarity such as personality traits. By the contrary, in the online dating context, Ramirez, et al. (2015) investigated what is the association between the amount of time spent online before meeting the potential candidate FtF, a hierarchical regression model was conducted in five dimensions (i.e., intimacy, composure, formality, task social orientation, dominance) where a curvilinear association among the first four was found, and it indicated a significant association to suggest that online daters benefit from the interface if the time period of online interaction is brief. Basically, the longer time spent on online platform decreases the motivation to meet face-to-face because it dampen the perceptions of closeness because candidates start to seek more online information about a candidate. However, there is no longitudinal study that simultaneously includes both dating settings (i.e. FtF and Online) to compare how the manner in which a romantic relationship starts may impact further romantic relationship outcomes in the long term; since the current state of research lacks of this type of study, it is difficult to establish strong claims in favor or against online dating for the long run.

CONCLUSION

As online romantic conversations begin to evolve and take shape, scholars must continue to observe and examine online relational phenomena through the use of online dating apps, which will be the next ubiquitous trend in terms of technology use in the upcoming years due to the wide spread

smartphone presence (Gerlich, Drmheller, Babb & D'Armond, 2015). Through the use of personal pictures, emoticons and other tactical punctuations, nonverbal communication plays a crucial role in the development of Internet-based courtship behaviors. The popularity of online Tinder is better calibrated to interpersonal attraction than the values-infused and text-heavy quality of the typical online dating site or app, which places users in a critical shopping mindset rather than an orientation based solely on attraction. Moreover, research on online dating should include interface design understanding to bring in the level of 'affordance tuning' to human sensory system to perform a specific task (i.e. dating) to assess CMC popularity and impact on human behavior.

KEY TERMS AND DEFINITIONS

Affordances: “The perceived properties of the things that determine just how they could possibly be used” (Norman 1998).

Away Messages: The messages that one uses to indicate that they are away from the computer or unavailable to communicate online.

Computer Mediated Communication: The use of computer or computer technology to communicate with other individuals.

Emoticons: Nonverbal expressions that are expressed via text.

Internet Affinity: The desire to initiate a romantic relationship via the Internet.

Netiquette: The etiquette and manners that individuals use while on the Internet.

Online Dating: CMC technology designed to facilitate romantic relationships initiation by anticipating face-to-face interaction through the access to personal profiles without owners’ awareness.

Other World: The notion that something is not real.

Online Prosocial Behaviors

S**Michelle F. Wright***Pennsylvania State University, USA***William Stanley Pendergrass***American Public University System, USA*

INTRODUCTION

Over three billion people use electronic technologies (e.g., cell phones, the internet) everyday (Internet Live Stats, 2016). Although there are many investigations and news stories about negative online behaviors, less attention has been given to positive online behaviors. There are many opportunities to receive help or to perform prosocial acts through electronic technologies. This chapter focuses on online prosocial behaviors. The chapter includes eight sections:

- Section one provides the definition of offline and online prosocial behaviors.
- Section two examines the unique characteristics of the cyber context and how such characteristics are conducive to prosocial behaviors.
- Section three focuses on various online prosocial behavior, including helping through electronic groups, online mentoring, online donations to charities, virtual voluntarism, and helping in other electronic contexts (e.g., social networking sites).
- Section four investigates the value of online prosocial behaviors to the giver and receiver.
- Section five provides theoretical explanations for why people engage in online prosocial behavior.
- Section six describes solutions and recommendations for organizations wanting to harness electronic technologies for various helping opportunities.

- Section seven presents suggestions for future research on online prosocial behavior.
- The last section provides concluding remarks regarding the chapter.

BACKGROUND

Prosocial behaviors are defined as voluntary acts directed toward people or society (Eisenberg & Miller, 1987). Such behaviors may include helping, sharing, donating, and volunteering. Online prosocial behaviors can take various forms, including donating time and attention to electronic discussion boards and Wikis (e.g., Antin, 2011; Butler, Sproull, Kiesler, & Kraut, 2007), helping among corporate employees (e.g., Duranova & Ohly, 2016), helping players in computer games (e.g., Molyneux, Vasudevan, & de Zuniga, 2015), online mentoring (e.g., Cheng, Hanuscin, & Volkmann, 2016), sharing and contributing to open source software (e.g., Lakhani & Hippel, 2003), virtual voluntarism (e.g., Kim & Lee, 2014), and making charitable donations to organizations online (e.g., Bennett, 2006). There are various characteristics of the online environment that are favorable for helping online.

CHARACTERISTICS OF ONLINE PROSOCIAL BEHAVIORS

Online prosocial behaviors have some characteristics that set them apart from the same behaviors offline. Search engines make it easier to

DOI: 10.4018/978-1-5225-2255-3.ch614

find opportunities to help or receive help online (Sproull, Conley, & Moon, 2013). It is easier to give or receive help online because one's physical appearance or personal attributes do not influence other's opinions (Brennan, Moore, & Smyth, 1992). Individuals can use fake names or screen names and hide their identities online, which reduces stigmas associated with seeking help (Wright & Li, 2012). The online environment offers flexibility to individuals wanting to help or give help, allowing them to give help or receive help even with restricted schedules. There is high controllability over online prosocial behaviors. The online environment allows givers to choose when they want to help and if they want to help again without feeling pressured (Sproull et al., 2013; Wright & Li, 2012).

Although there are noticeable differences between online and offline prosocial behaviors, there are similarities. The relationship between the giver and receiver of prosocial behaviors in either environment can include strangers (e.g., Sproull et al., 2013), friends (e.g., Cornejo, Tentori, & Favela, 2013), and business colleagues (e.g., Duranova & Ohly, 2016). Prosocial behaviors are rewarding for givers in either social context (Butler et al., 2007; Eichhorn, 2008). Furthermore, prosocial behaviors can occur through formal and informal organizational institutions (Wright & Li, 2011). There is typically no expectation of direct reciprocity of prosocial behaviors in offline and online contexts (Sproull et al., 2013).

PROSOCIAL BEHAVIORS IN THE CYBER CONTEXT

This section presents a review of the literature on opportunities for prosocial behaviors via open source software and Wikis, electronic support groups, online mentoring, electronic fundraising and crowdfunding, virtual voluntarism, and other

technologies, such as social networking sites (SNS) and online gaming.

Open Source Software and Wikis

Online prosocial behavior began with IBM's sharing of their open source software code and the SHARE user group (i.e., an online association designed to provide technology professionals with continuing education). People can use the internet to volunteer and contribute code, documentation, and technical support to open source projects (Sproull & Kiesler, 2005). In 1991, a Finnish student posted a program on the internet and invited others to contribute their own code. This program was the beginning of Linux. Its development still continues today and is largely voluntary. Other source code information is available for Mozilla, StarOffice, Apache webserver, Python, and the free BSD operating system (Barcellini, Detienne, & Burkhardt, 2009; Raymond, 1999). Some investigations have focused on people's motivations for providing help to open source code projects, with findings revealing that people were more likely to contribute to these projects if they valued the goals of the program and believed their time would benefit themselves and others (Hertel, Niedner, & Herrman, 2003; Lakhani et al., 2003). The sharing of open source software continues into the 2000s with improved technology, such as smartphones and Web 2.0 (Barcellini et al., 2009).

Similar to the sharing of open source software is the contributions people make to Wikis. Wikis or Wikipedias are websites that allow people to collaboratively edit its content (Antin, 2011). Antin (2011) examined the characteristics associated with contributing to Wikis. He found that assumptions about the type of person who contributes to Wiki content, either hacker or geek stereotypes, affect whether people participate. People were more likely to contribute to Wikis when they feel accomplished, felt like they were part of a

community, and believed the work allowed them freedom (Kuznetsov, 2006).

Electronic Support Groups

Clinicians recognized that the internet removes the boundaries and stigmas associated with help-seeking often present in the offline environment. Clients can receive support and advice about their illnesses over the internet without the fear of being judged. Although one of the first studies (i.e., Schneider & Tooley, 1986) on online help seeking did not specifically investigate online prosocial behaviors, it was one of the first to examine electronic technologies, specifically computer-based support groups, to help adults quit smoking. This study set the precedence for future investigations on electronic support groups.

Researchers have continued to investigate electronic support groups. In one study, Finholt and Sproull (1990) investigated prosocial acts through electronic groups among cooperate employees. Employees engaged in a variety of prosocial behaviors related to both work and outside of work activities. Research continues to focus on how electronic support groups contribute to employee satisfaction and organizational commitment (Duranova & Ohly, 2016; Ragsdale & Hoover, 2016). Other research has focused on providing support to special populations. In particular, Brennan and colleagues (1992) found that an electronic network helped caregivers of someone with Alzheimer's disease feel supported by individuals "who really understood what they were going through" (p. 668). Similarly, Hassett and colleagues (1992) found that an electronic support group increased disabled individuals' feelings of social support from other community members.

The benefit of social support and help received through electronic support groups has been recognized in other populations as well, including sexual abuse survivors (e.g., Finn & Lavitt, 1994), people living with AIDs/HIV (e.g., Mo & Coulson,

2013), individuals with disordered eating (e.g., Stommel & Meijman, 2011), individuals with epilepsy (e.g., Wicks et al., 2012), caregivers of premature infants (e.g., Thoren, Metze, Buhner, & Garten, 2013), parents of children with cancer (e.g., Coulson & Greenwood, 2012), hearing impaired individuals (e.g., Thoren et al., 2011), breast cancer patients (e.g., Chen, 2012), and couples dealing with infertility (e.g., Malik & Coulson, 2010). Findings from these studies revealed that electronic support groups are successful at connecting and supporting individuals within each of these populations. Research has continued to support the benefits of online support groups for various populations.

Online Mentoring

There are advantages for the mentoring of students and underrepresented populations online, such as providing access to professional expertise and assistance that may not be available in the mentees' community (Knapczyk, Hew, Frey, & Wall-Marencik, 2005). Mentor-mentee interactions can occur more frequently and at convenient times online (Ensher, Thomas, & Murphy, 2001). The online mentoring process also offers greater privacy and anonymity.

Given that women are underrepresented in technology related fields, like science and engineering, Bennett and colleagues (1998) hypothesized that online mentoring may be beneficial to female adolescents interested in these fields. Their findings revealed that female adolescents felt supported by their mentors and that their confidence had increased. Studies examining online mentoring provide support for improving the professional development of mentees through online mentoring programs (Cheng et al., 2016; Hooley, Hutchison, & Neary, 2016; McAleer & Bangert, 2011). Online mentoring has been used for various populations, such as college students (e.g., Barczyk, Buckenmeyer, Feldman, & Hixon,

2011), new teachers (e.g., Hutchison & Colwell, 2011), women entering management positions (e.g., Loureiro-Koechlin & Allan, 2010), adjunct faculty (e.g., Rogers, McIntyre, & Jazzar, 2010), and mental health professionals (e.g., Lee & del Carmen Montiel, 2010). These studies support the use of online mentoring.

Electronic Fundraising/Donating

With the increasing availability of the internet, it has become a convenient method to make and collect charitable donations. The American Red Cross raised \$1.3 million for the Kosovo crisis through their website and \$110 million was raised through online donations to help the victims of the September 11 attacks (Waters, 2007). Donations raised online for the 2004 Asian Tusanmi exceeded those raised through traditional methods (i.e., calling to pledge money). After the 2010 Haiti earthquake, the donations raised online or through text messages exceeded \$30 million within the first month (Heath, 2010). Other researchers have examined the motivations behind donating to electronic charities. Olsen and colleagues (2001) found that successful nonprofit organizations raised funds by expressing to the donors how the gifts will help specific people. Furthermore, Bennett (2006; 2009) and Eller (2008) found that holding a positive attitude toward a population in need and having prior knowledge of the population were related to donating more money to that population.

Another mechanism for online donations is crowdfunding. Crowdfunding involves raising money from the general public to fund a project (Chen, Thomas, & Kohli, 2016). It works by having someone initiate the idea or project to be funded (Ordanini, Miceli, Pizzetti, & Parasuraman, 2011). Next, individuals support the idea and then the system for collecting donations brings these people together to execute the idea or project.

There were \$5.1 billion raised in 2013 through crowdfunding (Broderick, 2014). Regardless of where money is donated, people are making monetary contributions online to man-made and natural disasters, projects, and ideas.

Virtual Voluntarism

Many websites advertise various online voluntarism opportunities (Spencer, 2002). One of the first investigations to examine virtual voluntarism, the Virtual Volunteering Project, assessed the experiences of almost 200 agencies (Cravens, 2000). Findings from the project revealed that clearly written task descriptions and good communication are essential for keeping volunteers engaged with the organization. Haase and colleagues (2002) further investigated the characteristics of individuals who participated in virtual voluntarism. Volunteers were typically well educated, watched less television, and engaged in an active lifestyle. Other researchers (e.g., Butler et al., 2007) have examined ways to keep volunteers active through online organizations, with findings revealing that websites should be easily accessible to volunteers and that organizations should make their opportunities more fulfilling for volunteers.

Some researchers have considered how organizations can harness the power of social media for virtual voluntarism. In one study, Raja-Yusof and colleagues (2016) examined the activities that volunteers engaged in via social media. The major activity was knowledge sharing, with less time spent on training, fundraising, and problem-solving. Other research has focused on volunteer characteristics. In particular, Kim and Lee (2014) found that social capital and subjective norms predicted volunteering via SNS. The popularity of SNS has created many opportunities for volunteering. Furthermore, organizations should understand how they can attract and maintain volunteers committed to their organizational mission.

Other Electronic Technologies

The popularity of SNS, such as Facebook and Twitter, and online games has generated researchers' interest in prosocial acts through these technologies. Some investigations have provided evidence that gamers are more likely to help other players when they are altruistic and engage in offline prosocial behaviors (Ferguson & Garza, 2011; Molyneux et al., 2015; Wang & Wang, 2008). Sudzina, Razmerita, and Kirchner (2011) found that playing online games helped alleviate daily stress when these individuals received help through Facebook games. Other investigators have examined broader forms of online prosocial behaviors. For instance, face-to-face prosocial behaviors was associated positively with prosocial behaviors via SNS, chat programs, email, and text messages (Wright & Li, 2011).

VALUE OF ONLINE PROSOCIAL BEHAVIORS

There are benefits of online prosocial behaviors to the receiver. For example, receivers report health benefits from their participation in online support groups (e.g., Brennan et al., 1992), feel stress relief after receiving online gifts through Facebook games (e.g., Sudzina et al., 2011), and receive support and gain confidence from online mentors (e.g., Loureiro-Koechlin & Allan, 2010). Receivers benefit from the creation of relationships with users in online communities (Cummings et al., 2002). These online relationships offer receivers social support and advice. There is also evidence that online prosocial behaviors benefit the helper. Helpers gain personal satisfaction and support within their online communities and health benefits through virtual voluntarism (e.g., Butler et al., 2007; McAleer & Bangert, 2008; Mukherjee, 2010). Furthermore, contributors to open source software support groups reported learning and reputational benefits after helping others with questions (Hertel et al., 2003; Lakhani & Hippel, 2003).

THEORETICAL FRAMEWORKS

Social Cognitive Theory

The social cognitive theory suggests that online prosocial behaviors are learned by observing other people (Bandura, 1977). Newcomers may visit a discussion group for a while before posting, allowing them to get an idea about what messages are viewed as helpful. This information is then utilized when posting messages. If the post is rewarded with praise, newcomers might further contribute to the community. Supporting this idea, McKenna and Bargh (1998) found that a positively evaluated response contributed to newcomers' active involvement in the electronic discussion group. Positive reinforcement encourages contributions to the electronic community.

Co-Construction Theory

The co-construction theory was proposed to explain the construction of offline and online identities. Adolescents construct their online identities similar to their offline identities (e.g., Boneva, Quinn, Kraut, Kiesler, & Shlovski, 2006; Huffaker & Calvert, 2005; Whitlock, Powers, & Eckenrode, 2006). The co-construction theory has been applied to online prosocial behaviors. Wright and Li (2011) explained that online prosocial behaviors occur because people generalize their prosocial disposition to the digital environment.

Both the social cognitive and co-construction theories explain why individuals engage in and experience online prosocial behaviors. Both theories provide a valuable framework for understanding the continued involvement in prosocial behaviors and under which conditions people ask for help online.

SOLUTIONS AND RECOMMENDATIONS

While online prosocial behaviors may not receive as much attention as harmful online behaviors,

these behaviors are important to society. Online prosocial behaviors are important and need to be recognized for their benefits. The quality of help received online is an important factor for organizations to consider. In their review of prosocial behaviors through electronic discussion groups, Sproull and colleagues (2013) argued that the quality of help received online should be examined as it might help determine the value to the helper and receiver. Bad advice does not benefit the receiver and it can ruin the helper's reputation. Receiving good advice may relate to the desire to seek help again and determine whether individuals will give advice at another time. Online prosocial behaviors can promote social justice, assist individuals in need, heal and help the wounded, and elevate the level of good in the world. As such, online prosocial behaviors should be recognized for its benefit and promoted.

FUTURE RESEARCH DIRECTIONS

Most research on online prosocial behaviors is cross-sectional. Consequently, changes overtime in online prosocial behaviors are not well understood. Understanding attributional patterns of the helper and receiver is another important direction as attributional patterns relate to future behaviors. Such a research direction might allow researchers to predict when individuals will ask for help and when individuals will give help online.

Individual differences are also important to consider in regard to online prosocial behaviors. Certain characteristics, such as those with high social and emotional competence, empathetic concerns, self-esteem, and the desire to be part of the group may help to explain why individuals act prosocially online. Cultural values may also be important to consider. Collectivism may encourage online prosocial behaviors to maintain group cohesiveness, whereas individualism may encourage the use of online prosocial behaviors to achieve personal goals. Cross-cultural and intra-

cultural investigations linking cultural values to online prosocial behaviors may shed light on the characteristics associated with such behaviors.

CONCLUSION

There are a variety of opportunities to help and receive help in the multi-faceted online environment, including contributing to open source software and Wikis, online mentoring, virtual voluntarism, online donating/fundraising and crowdfunding, and providing support or receiving support through online support groups. People act prosocially toward others or ask for help online for a variety of reasons. Although research on online prosocial behaviors is developing, many areas await investigation. Online prosocial behaviors balance individuals' online experiences.

KEY TERMS AND DEFINITIONS

Co-Construction Theory: This theory proposes that people's identities are constructed in similar ways online and offline.

Online Donating/Fundraising: Online donating and fundraising involves raising money or

accepting donations via electronic technologies and the internet.

Online Mentoring: Online mentoring involves someone (the mentee) receiving knowledge on a topic or career via electronic technologies and/or the internet by an expert (the mentor).

Online Prosocial Behaviors: Online prosocial behaviors involve helping, sharing, donating, and volunteering that is carried out via electronic technologies and the internet.

Online Support Groups: Online support groups allow people with the same challenges to connect via electronic technologies and/or the internet.

Open Source Software: Open source software is software in which the source code is available to others for modification or enhancement.

Prosocial Behaviors: Prosocial behaviors are acts that involve helping, sharing, donating, and volunteering.

Social Cognitive Theory: This theory states that people's knowledge and behaviors are related to their observations of others.

Virtual Voluntarism: Virtual voluntarism involves using electronic technologies and/or the internet to assist an organization.

Online Social Networking Behavior and Its Influence Towards Students' Academic Performance

Maslin Masrom

Universiti Teknologi Malaysia, Malaysia

Selisa Usat

Universiti Teknologi Malaysia, Malaysia

INTRODUCTION

Online social networking (OSN) is an online application that has grown rapidly in prevalence and popularity in recent years. Millions of Malaysian youngsters, teenagers, students (either at school, college or university's level) use OSN websites such as Facebook, Twitter, Myspace, Friendster and LinkedIn every day. Besides, Malaysian higher education also has adopted OSN on a wider scale and young Malaysians are very active users of OSN (Zakaria, Watson, & Edwards, 2010). In other words, the use of online social network has become necessary among younger generation.

The emergence of online social network has become a major trend over the years with growing popularity amongst the younger generation (Onuoha & Saheed, 2011). When online social networking becomes more popular, literature, however, suggests that there is an ongoing debate on the role of online social networks in the academic performance of users.

This article synthesizes the literature review concerning use of OSN in school, college and university, and academic performance of students. It offers definitions of OSN, followed by the status of current knowledge about the use of OSN and academic performance of students. Based on the secondary sources, it concludes the entry with recommendations for future research direction on the relationship between use of OSN and academic performance.

BACKGROUND

Online social networking sites (OSNs) are websites that give users a range of services based on web technologies that allow individuals to build a public or semi public profile with relationships system, have a list of other users with whom they share a connection, and finally, view and navigate through the list of users' connections with those who share a connection in the system (Boyd & Ellison, 2007).

OSNs are also defined as a range of activities enabled by social technologies or social media tools include blog, microblog, wiki, social networking site, video sharing site and online discussion board or forum, and operationalized by a group of people (Hamid et al., 2009). It enables users to socialize and create networks online. Examples of OSNs that are used on a regular basis by millions of people nowadays are Facebook, Twitters, MySpace, Friendster, Youtube and Skype. Ahmed and Qazi (2011) meanwhile cited that, the most successful and largest social networking site is Facebook with more than 500 million members had been found as active users of Facebook in July 2010. In Malaysia, social interaction in cyberspace by using social networking has been adapted by many people and has changed their communication (Mustafa & Hamzah, 2011).

We define online social networking as the latest online communication tool that allows users to create a public or private profile to interact

with people in their networks, share their profile information, communicate with others, and share data and information within that system.

The social technologies can support interaction among students by allowing them to actively participate in a discussion. The students can work collaboratively in an online social environment to solve problems with their peers, or to organize social events. The collaborative production's principle embedded in social technologies enable learners and teachers to share and publish artifacts produced as a result of the learning activity (for example, course materials such as course syllabus, course notes and assignments). In this regard, the use of social technologies has changed the demand of education.

Online social networking can be classified into five categories (Fraser & Dutta, 2008), namely, (i) egocentric networks - act as a platform to build a network of friends; (ii) web communities - collecting members with identity ties based on interest, gender, race, nation, religion and others; (iii) opportunistic web – the members gathered for business purpose or professional relationship using OSN site such as LinkedIn; (iv) passion-centric network – gathered people who share interests or hobbies (communities of interest); and (v) media-sharing site – this site is defined based on its contents (such as Youtube for those who want to share videos).

Students are increasingly using these social networks for friends' news feeds, personal updates, events and activities, notes, and messages. According to Michael, Robyn and Kate (2013) the widespread use of media among college students from texting to chatting on cell phones to posting status updates on Facebook may be taking an academic toll. They found media use, in general, was associated with lower grade point averages (GPAs) and other negative academic outcomes. Thus, this has led to a rise of below question:

Can the extensive use of OSNs in the younger generation affect students' academic performance?

The issue of whether OSN give positive or negative impact on students' academic performance is often dependent on the larger issues identified with the overall use of OSN sites such as individual self-discipline and self-regulation (behavior in terms of time spent on- and off-line), psychological effects and user adaptability (Egedegbe, 2013).

STUDENTS' PRACTICES OF OSN AND BEHAVIOR

The most used features by OSNs users are: uploading and sharing photos and videos, comments on other profiles, friends and private messages between users. In this context, users of OSN sites also share a number of documents, and interact and communicate with each other. What makes the OSNs unique, not because they allow students or users to meet others in the network, but because they make possible for students to manage and make visible their own social network (Fardoun et al., 2012).

The teenagers and youth especially students have embraced online social networking as one method to connect with their friends, share information and showcase their social lives (egedegbe, 2013). In general, the students spend a lot of time on OSN sites creating their profile, doing research concerning their academic assignments or works, chatting with friends and posting pictures of event they attended. Young et al. (2009) found that students keen on interacting with others in order to exchange information about their interests, to discuss about interesting or new topics and follow news about certain topics on OSN sites.

USE OF ONLINE SOCIAL NETWORKING

Online social networking can be regarded as a platform allowing teachers and students to com-

municate and collaborate on school subjects and projects outside the classroom (Khedo et al., 2012). According to Khedo et al. (2012), teachers can post school related works on these online communities and students can enrich their learning experiences by teaming up with their class mates to work on assignments and projects. These networks can also go beyond the classroom walls by uniting multiple classrooms from different schools, thus creating a richer environment for collaboration and knowledge sharing.

Hamid et al. (2011) have investigated the impacts of the use of OSN on enhancing student engagement and interaction from the students' perspectives. Their findings revealed that students showed positive inclination towards the use of OSN in facilitating their learning. The OSN benefited the students in enhancing their engagement and interaction, in promoting critical thinking, discovering new knowledge, tracking their own learning progress and being a platform to be more vocal.

In general, benefits of OSN use for students' education purpose among others are as follows:

1. The use of OSN has significant potential to support and enhance in-class teaching and learning (Arnold & Paulus, 2010; Techehaimanot & Hickman; 2010; Kabilan et al., 2010);
2. Increase student interaction with other students and their lecturers via electronic medium;
3. Increase student-to-student and student-to-lecturer interaction outside of traditional class time (Arnold & Paulus, 2010; Gray, Chang, & Kennedy, 2010);
4. Increase students' satisfaction with the course;
5. Improve students' learning and writing ability;
6. Provide greater access to information and information sources.

Other benefits associated with the use of OSN for other purposes are (Mozee, 2012; Connolly, 2011; Zwart et.al, 2011; Rosen, 2011):

1. Encouraging creativity among and between individuals and groups;
2. Creating a sense of belonging among users of common social media tools;
3. Providing more choices to promote engagement among different individuals and groups;
4. Reducing barriers to group interaction and communications such as distance and social or economic status;
5. Increasing the technological competency levels of frequent users of social media.

According to Rosen (2011), the daily use of all online social media technologies for those born between 1965-1979 (Generation X) consumed approximately 13 hours of social media per day; those born between 1980-1989 (Net Generation or Generation Y) consumed approximately 19 hours of social media per day; and those born between 1990-1999 ('I Generation') consumed approximately 20 hours of social media per day.

ACADEMIC PERFORMANCE

There has been considerable discussion regarding the frequent use of OSN sites by high school and college students, and the possible effect of those tools on students' academic performance (Connolly, 2011; Hargittai & Hsieh, 2010; Karpinski, & Duberstein, 2009). With the increased number of young users, it is presumed that OSNs may have some impacts on college students' academic performance, lifestyle, and personal development (Tham & Ahmed, 2011). The frequent involvement of students (at school, college and university level) who constitute a huge percentage of young people in online social networking has, however, led to deliberations on how their academic per-

formance could be affected due to their taking part in this activity.

Based on their findings, Onuoha and Saheed (2011) recommends that: (1) for students who find the use of online social networks distracting to academics, there is need to reduce the time spent on these networks; and (2) time spent on online social networks should be devoted more to academic than social matters in order to make maximal use of its education potentials.

Academic performance usually appears in research into education and educational psychology (Rouis, Limayem, & Salehi-Sangari, 2011). According to Rouis et al., there are two main approaches that offer different visions of academic performance, that is, (i) approaching a specific goal but avoiding adverse outcome offers an alternative, and (ii) goal achievement focused on the task or final results (Valle et al., 2009). Since OSNs use is considering as a leisure activity that interrupts students' academic performance, an effect is presumed on students' overall academic results or grades of the students. In this context, the conceptualization of academic performance is results focused, and therefore focuses only the final results or grades of the students.

THE RELATIONSHIP BETWEEN THE USE OF OSN AND ACADEMIC PERFORMANCE

There is a growing concern whether OSN use is contributing to a decline in academic performance by school, college or university students. Many students stated sparing time with media or online social networking sites take away time from completing homework. This issue can be viewed as a form of displacement. Students saw OSN use as being a hindrance to academic performance when it displaced the quantity of time spent studying. Karpinski (2009) showed that college students who use Facebook often spend less time studying and have lower grade point averages (GPAs) compared to students who have

not signed up for the social networking website. Thus, the relationship between the use of OSN and academic performance of student is one issue that is essential to be measured based on various degrees the level of OSN use and the academic performance level of the user.

Regard to the relationship between the use of OSN and academic performance, the findings of some past studies are listed as following:

- Stollak, Vandenberg, Burklund, and Weiss (2011), Rouis, Limayem, and Salehi-Sangari (2011), Karpinski and Duberstein (2009), and Canales, Wilbanks, and Yeoman (2009) found a negative effect; that is, higher use of OSN typically leading to lower academic performance as measured by grades;
- Ahmed & Qazi (2011) and Hargittai and Hsieh (2010) found either no-to-little relationship between the use of OSN and student academic performance;
- Pasek and Hargittai (2009), Junco, Heiberger, and Loken (2011), and Rizzuto, LeDoux, and Hatala (2009) found a positive effect; that is, the use of OSN leading to an increase in student academic performance;
- In his article, Social Networks in Nigeria, Oche (2010), stated that the recently released results for the National Examination Council (NECO) showed that 87% of the candidates failed English Language and Mathematics which the author attributed to use of Facebook;
- Vanden Boogart (2006), in a similar study also found out that lower GPAs is associated with heavy use of Facebook (i.e., more time spent on Facebook);
- Kolek and Saunders (2008) in a study of students from a public Northeast research university found out that there was no correlation between Facebook use and GPA;
- Hahhad M. (2013) study using sample which consisted of undergraduate students

enrolled in fall 2012 courses at California State University of Monterey Bay concludes that there was a weak correlation between GPA and time in regards to the three variables age, gender and major;

- Junco (2015) in his recent studies on undergraduate students showed that seniors spent significantly less time on Facebook and spent significantly less time multitasking with Facebook than students at other class ranks. Time spent on Facebook was significantly negatively predictive of GPA for freshmen but not for other students. Multitasking with Facebook was significantly negatively predictive of GPA for freshmen, sophomores, and juniors but not for seniors.

Other factors that are also should be considered on measuring the relationship of OSN and students' academic performance include the frequency and intensity of social media usage; the personality type of the social media user (for example, extroverted, introverted); the socioeconomic and cultural background of the user; the ability of the user to self-regulate their behavior in terms of time spent on- and off-line; the differences among the social networking sites in terms of their content, purpose, and structure; and the academic ability of the social media user (Mozee, 2012).

CONCLUSION

Online social networking sites are not only emerging as important tools in today's schools, but they also provide very popular out-of-school computer activities among students and/or young adults. It represents a potential technology that can be exploited to enhance learning in order to help students in their education. The academic performance can have long-term consequences for society and the individual in terms of overall quality of life

(Phusavat, Ketsarpong, Ooi, & Shyu, 2012). The research literature indicated that for some students the use of social media can be beneficial and/or harmful to their academic performance, and for other students it appears to have no effect. The school teachers and college and university's lecturer need to look at the relationship between students' practices on social network sites and their academic learning, and to keep creating a vision of continual technology integration in their classrooms (Greenhow & Burton, 2011). Online networks can be used for academic purposes such as peer-to-peer knowledge sharing and collaboration. In this respect, the school teachers and college or university's lecturer need to recognize the power of OSNs in college students' academic learning. In future, using mixed methods educators could understand how online social networking changes their educational attainment and students' academic performance.

FUTURE RESEARCH DIRECTIONS

Future research should (1) identify the level use of OSN among students; (2) examine the effect of OSN' use to academic performance as measured by grades; and (3) investigate the relationship between the use of OSN and student academic performance.

KEY TERMS AND DEFINITIONS

Academic Performance: The academic performance is defined by students' reporting of past semester CGPA/GPA and their expected GPA for the current semester. The grade point average or GPA is now used by most of the tertiary institutions as a convenient summary measure of the academic performance of their students. The GPA is a better measurement because it provides a greater insight into the relative level of performance of individuals and different group of students.

Facebook: Facebook is a popular online social networking site or service that offers an online platform on which users create profiles, generate and share contents and information, and interact with other contacts.

Friendster: Friendster is an online social network site where we can meet people online, find new and old school friends and play games.

MySpace: MySpace is online social networking sites that allow users to create webpages to interact with other users. Then, users are able to create blogs, upload videos and photos, and design profiles to showcase their interests and talents.

Online Social Networking Sites: Online social networking sites (OSNs) generally refer to Internet-based locations that allow individuals and groups to interact. Specifically, it refers to those Internet-based services that: promote online social interaction between two or more persons within a bounded system for the purposes of friendship, meeting other persons, and/or exchanging informa-

tion; contains a functionality that lets users create public or semi-public personal profile pages that contain information of their own choosing; serves as a mechanism to communicate with other users; and contains mechanisms that allow users to search for other users according to some specific criteria. Examples of the most visited OSNS are Facebook, Twitter, Youtube, Friendster, Myspace, and LinkedIn.

Online Social Networking: Online social networking is defined as the latest online communication tool that allows these users to create a public or private profile to interact with people in their networks.

Social Media: Technologies that facilitate social interaction, make possible collaboration, and enable deliberations across stakeholders.

Twitter: Twitter is an online social networking and microblogging site or service that enable users to send and read tweets (text messages).

Parental Mediation of Adolescent Technology Use

S

J. Mitchell Vaterlaus

Montana State University, USA

INTRODUCTION

Adolescence is a developmental time period marked by physical (e.g., puberty), psychological (e.g., identity formation), and psychosocial (e.g., negotiation of parent-child relationships) changes (Erikson, 1950, Grotevant & Cooper, 1986). Puberty is typically seen as the beginning of the adolescent developmental time period, although there is some disagreement regarding when adolescence ends (Bynner, 2007). Hall (1904), an early developmental scholar, posited that adolescence continued into the early twenties, and some current scholars have supported this proposition because the developmental tasks of adolescence are continuing into the mid-twenties (Shwartz, Côté, & Arnett, 2005). Consistent with these historical and contemporary conceptualizations (Bynner, 2007; Hall, 1904; Shwartz et al., 2005), in this chapter adolescence is defined as the time period between the onset of puberty and until the individual reaches their mid-twenties.

Contemporary adolescents have grown up with access to a variety of technologies. The majority of adolescents (13-17 years old) in the United States have access to cell phones (88%) and computers (87%), and 92% of adolescents report going online daily (Lenhart, 2015). Adolescents are the most frequent users of social media and 71% report using more than one social media site (Lenhart, 2015). Parents, too, are technology consumers with 91% reporting that they use the internet and 83% using social media. Technology appears to have become a normative aspect of family life, but parents and adolescents use technology differently (Vaterlaus & Tulane, 2015). Parents primarily use technol-

ogy for instrumental purposes (e.g., cell phones to track location of child), while adolescents use technology for social reasons (e.g., cell phones to build social relationships).

As interactive technologies (e.g., cell phones, social media) have become a common feature during adolescence, parents have reported concerns about these technologies. Concerns about adolescent technology use have included worry about the potential psychological outcomes from viewing content (e.g., violent or pornographic), the risk of victimization, and access to illegal activities (e.g., illegal file sharing; boyd & Hargittai, 2013). Because of these concerns for children and adolescents, some limited government policy has emerged regulating website use among minors (Costello, McNiel, & Binder, 2016). For example, the United States' Children's Online and Privacy Protection Act (COPPA; Federal Trade Commission, 2016) requires parental permission for websites/online services to collect or use personal information from children under the age of 13. This particular policy has been criticized because it does not account for the privacy risks for adolescents older than 13 (Costello et al., 2016) and it is difficult to regulate with minors commonly falsifying their ages to access websites (O'Keeffe & Clarke-Pearson, 2011). "As legal regulations in this [technological] sphere are difficult to formulate and enforce, policy makers rely substantially on increasing risk awareness among parents and delegating to them the responsibility for protecting children from online risks." (Kirwil, 2009, p. 394). To mitigate the potential negative effects and facilitate the potential positive effects of adolescent interactive technology use, some parents

DOI: 10.4018/978-1-5225-2255-3.ch616

have made attempts to be involved in their adolescents' technology use. These parental attempts have been researched under the term *parental mediation*, which refers to parental interventions and interactions with their adolescents regarding technology use (Livingstone & Helsper, 2008; Vaterlaus, Beckert, Tulane, & Bird, 2014).

BACKGROUND

The early research on parental mediation focused on parent's attempts to mediate children's television viewing (Austin, 1990; Nathanson, 1999). Dr. Amy Nathanson (Nathanson, 1999), of The Ohio State University, has been a leader in identifying the methods parents have used to mediate children's television viewing. Dr. Sonia Livingstone (Livingstone & Bober, 2006), of the London School of Economics and Political Science, is a pioneer in researching the role of parental mediation with interactive technologies—publishing on parental mediation of children and adolescent's internet use. Additionally, Dr. Laura Padilla Walker and Dr. Sarah Coyne (Padilla-Walker & Coyne, 2011), of Brigham Young University, have made recent contributions to the understanding of the implementation of parental mediation with adolescent interactive technology use.

The evolution of technology has led to technological convergence, which allows a single media source to be accessed from several devices. Brooks-Gunn & Donahue (2008) explained:

Thanks to convergence, a teen can watch a television show on a computer long after the show has aired on television and can use a cell phone to surf the internet. Children, particularly adolescents, thus have almost constant access to media—often at times and in places where adult supervision is absent. (p. 3)

Because interactive technologies facilitate private access to a variety media and digital social opportunities, parents have voiced their concerns

about adolescent interactive technology use (Boyd & Hargittai, 2013) and some have sought ways to reduce the potentially negative effects of adolescents use through parental mediation (Livingstone & Helsper, 2008; Vaterlaus et al., 2014). The term parental mediation represents several different strategies for parental involvement in adolescent technology use. It is important to note that not all researchers in this area of study have adopted the term parental mediation. For example, some prefer “proactive media monitoring” because the implemented parental strategies “may not mediate media effects rather, they may prevent them from occurring in the first place or may protect [adolescents] against them” (Padilla-Walker, Coyne, Fraser, Dyer, & Yorgason, 2012, p. 1154). Regardless of the broader term used to describe parental involvement in their children's technology use, researchers have identified congruent strategies parents use which include: active mediation, restrictive mediation, and co-viewing (Livingstone & Helsper, 2008; Nathanson, 2001). This chapter summarizes different parental mediation strategies, details parent and adolescent perceptions related to parental mediation, and explores the challenges in implementing parental mediation.

CURRENT SCIENTIFIC KNOWLEDGE IN PARENTAL MEDIATION

Parental Mediation Strategies

Parental mediation of adolescent interactive technology use has been investigated with both quantitative (Livingstone & Helsper, 2008) and qualitative (Vaterlaus et al., 2014) research methods. The term parental mediation is representative of a range of strategies parents use to influence their adolescent's technology use. Nathanson's (1999, 2001) early work with parental mediation and children's television viewing provided some broad strategies that parents implement, which include: (a) active mediation, (b) restrictive mediation, and (c) co-viewing. Parents implement

variations of these television parental mediation strategies for adolescent interactive technology use (Livingstone & Helsper, 2008; Vaterlaus et al., 2014). The adapted parental mediation strategies for adolescent interactive technology use can be discussed in terms of active mediation, restrictive mediation, and monitoring strategies.

Active Mediation

The process of active mediation has been described as parents engaging adolescents in “discussions regarding questionable content in the media, and offer[ing] strategies and ways in which children might be more aware of this content, or might avoid it” (Padilla-Walker et al., 2012, p. 1154). At the heart of this strategy is parent-child discussion. The parental mediation strategy of co-viewing (e.g., watching television with a child; Nathanson, 2001) or co-use may not intuitively fit within broad category of active mediation because co-use could include little discussion. Livingstone and Helsper (2008) provide support for inclusion of co-use within the category of active mediation:

Parents and children may watch television together with little conversation (i.e., co-use), perhaps with the parent also reading the paper while the child does their homework in front of the screen. However, to sit together in front of the computer while the child goes online, or even to be in the same room, makes co-use more active, for conversation about the online activity, including interpretive or evaluative comments or guidance, is more likely. (p. 589)

Livingstone and Helsper (2008) reported that active mediation was the most widespread technique parents ($n = 905$) implemented for mediating adolescent internet use. Active mediation was evidenced by parents talking to their adolescent about their internet use or by watching the screen and staying in the vicinity of the computer while the adolescent was on the internet. Vaterlaus and colleagues (2014) asked parents ($n = 80$) and

adolescents ($n = 113$) to describe how parents mediated adolescent interactive technology use (i.e., internet and cell phone use). Parents and adolescents reported that the second most frequent mediation technique was active mediation—parents mediated by asking their adolescent who they were communicating with or what they were accessing via technology. Participants also indicated that parents were friends with their children on social media sites and in some instances used the internet together. Padilla-Walker and colleagues (2012) reported in their longitudinal study that active mediation was the most common approach among a sample of 276 of mother-adolescent dyads, but the mother’s use of the strategy decreased as the adolescent aged. Parenting qualities were found to be predictive of the use of active mediation in a study with 478 families (Padilla-Walker & Coyne, 2012). Parents who demonstrated connection (e.g., responsiveness to adolescents needs) and regulation (e.g., emphasize the importance of rules) were more likely to implement increased levels active mediation when compared to other parents.

Restrictive Mediation

Parents who use restrictive mediation block access to interactive technology or implement limits on adolescents interactive technology use (Vaterlaus et al., 2014). In a qualitative study, parents and adolescents reported that restrictive mediation included preventing adolescent ownership of cellphones or blocking specific features (e.g., text messaging, apps) on technology (Vaterlaus et al., 2014). Others reported implementing content (e.g., internet filters), time (e.g., internet access blocked after a certain time), and location restrictions (e.g., computer located in a public place). Padilla-Walker and Coyne (2011) identified that parents who had the parenting quality of regulation (e.g. emphasize the importance of the rules) implemented higher levels of restrictive mediation. Also, in a longitudinal study with mother-adolescent dyads, Padilla-Walker and colleagues (2012) found that

restrictive mediation strategies decreased as the adolescent aged.

Livingstone and Helsper (2008) discussed restriction in terms of interaction restriction (i.e., preventing peer-to-peer social facilitation through technology by banning email, instant messaging, or like features) and technical restriction (i.e., blocking activities through the use of filters or parental controls). The practice of restricting interactions was the only parental mediation technique Livingstone and Helsper (2008) identified that was associated with decreasing adolescents' online risks. The researchers cautioned that the sociability facilitated by the internet is a major appeal among adolescents, so blocking interactions may be keeping "teenagers safe at a cost" (p. 597). Lee (2013) identified similar benefits for the implementation of restrictive mediation with Korean mother-adolescent dyads ($n = 566$). Maternal implementation of restrictive mediation was associated with decreased time spent online and lower online risks among adolescents.

Monitoring

The practice of monitoring is defined as "checking up on the child's [internet] activity, covertly or overtly, after use" (Livingstone & Helsper, 2008, p. 589). This was the most frequently reported parental mediation technique in the Vaterlaus et al. (2014) study—participants reported that monitoring involved parents checking adolescents' digital footprint, which included checking things like internet history, text messages, and pictures. In terms of cell phone use parents and adolescents specifically talked about parents monitoring the number of minutes and amount of data used on the cell phone bill. In their comparison between online risks and various parental mediation strategies, Livingstone and Helsper (2008) found no significant relationship between monitoring internet use and decreased online risks for adolescents. Further, there is some evidence that the more parents monitor adolescent internet use the more adolescents do to prevent parent's attempts

to uncover their online activities (Livingstone & Bober, 2006).

Perceptions of Parental Mediation

Parent-Adolescent Discrepancies

Differences have been documented in reports of parental mediation of adolescent internet use between parents and adolescents in the same household (Livingstone & Bober, 2004; Wang, Bianchi, & Raley, 2008). Vaterlaus and colleagues (2014) asked parents and adolescents to report the implementation of parental mediation of adolescent internet use within the same household. Mothers and fathers reported significantly more parental mediation of adolescent internet use when compared to their adolescents' reports. Similarly, Fletcher and Blair (2014) reported that some families experience conflicted parental authority when technology rules are not clearly communicated to the adolescent—resulting in parents and adolescents having different perspectives of parental mediation of adolescent technology use. Livingstone and Bober (2004) postulated that these differences between parents and adolescents may result from generationally different perceptions of the technology rules in the household. Parents may report the official rules without addressing the potential exceptions, while adolescents interpret the rules differently because of the exceptions granted by parents. Adolescents seem to follow their own interpretations of parental technology rules.

Privacy, Authority, and Trust

Parents and adolescents have different perspectives regarding the purpose and use of interactive technologies (Vaterlaus & Tulane, 2015). Oksman and Turtiainen (2004) reported discrepancies between Finnish parents' and adolescents' motivations for cell phone ownership. Parents view adolescent cell phone ownership as a way to increase security (e.g., monitoring teen's location) and adolescents are motivated by wanting to use the device to stay

in contact with their friends. New technologies are often preferred by adolescents because of the privacy they afford. For instance, Oksman and Turtiainen (2004) concluded, “For teenagers, text messaging is a quiet and simple way to maintain their social network without their parents’ knowledge” (p. 336). Adolescents may oppose parental mediation strategies because the practice could be perceived as a violation of privacy:

Children relish the opportunities the internet affords them—for identity play, relationships, exploration and communication—and may not wish to share this experience with their parents. (Livingstone & Bober, 2004, p. 43)

Granting adolescents access to interactive technology and then implementing parental mediation could also be perceived as a violation of parental trust. Vaterlaus and colleagues (2014) qualitatively explored adolescents’ perceptions of parental mediation practices. Approximately half of the adolescents (47%) indicated that parents had the authority and responsibility to mediate their adolescents’ interactive technology use, but then explained how parental trust needed to be part of the equation. Adolescents clarified that parental mediation techniques should be implemented when an adolescent gained access to a new technology and then mediation practices should decrease as the adolescent gained parental trust. Adolescents also recommended that parents communicate with them openly about parental mediation and include adolescents in establishing the parental mediation practices in their home.

Challenges in Parental Mediation

Digital Generation Gap

Parents do experience challenges in their attempts to regulate their youth’s media use because of the privacy afforded by new technologies and the technological expertise required with the evolving technologies (Livingstone & Helsper,

2008). Vaterlaus and Tulane (2015) concluded that there are generational differences between parents and adolescents in their conceptualizations of the purpose and use of technology (e.g., instrumental vs social purposes), where they learn about technology (e.g., parents often rely on children to teach them), and in knowledge of how to use technology. A difference between parents and adolescents in knowledge about how to use technology is referred to as a digital generation gap (Livingstone, 2003, Vaterlaus & Tulane, 2015). One study documented that late adolescents ($n = 555$) perceived that they knew significantly more about how to use interactive technology (i.e., cell phones, social networking, email, and video chat) than their parents (Vaterlaus, Jones, & Tulane, 2015). Parents ($n = 604$) in the study also rated their own knowledge about interactive technologies significantly lower than their late adolescents’ knowledge.

The presence of a digital generation gap could challenge the traditional top-down (parent to child) socialization patterns in families, which may make it challenging to implement parental mediation strategies (Correa, 2014). Parents often report that they do not know what their children are doing online and feel at a loss in how to help them use the internet in positive ways (Livingstone & Bober, 2004). Having more technological knowledge may allow adolescents to evade parental attempts at mediation. For example, a study conducted with teens in the United Kingdom, reported that the teens had implemented efforts to maintain their privacy from their parents through deleting emails, clearing internet history, or minimizing screens when someone came into the room (Livingstone & Bober, 2004). Parents’ lower levels of technological expertise may limit the types of mediation that they implement or prevent the implementation of parental mediation at all. Parents implement a variety of attempts to mitigate the potentially harmful impacts of adolescents’ internet use, but it appears that parents have a preference of using co-use over approaches that may require more technological expertise (i.e.,

restriction or monitoring; Livingstone & Bober, 2004). Fletcher and Blair (2014) interviewed 20 adolescents (seventh grade students) and their mothers regarding mothers' authority over their adolescents' interactive technology use. Mothers who reported limited expertise with a technology were more likely to report that they did nothing to mediate their adolescent's use of that technology.

Parental Mediation in Later Adolescence

One of the major tasks during adolescent development is developing autonomy from parents (i.e., becoming independent while still maintaining connection with parents; Zimmer-Gembeck & Collins, 2003). Following completion of high school many adolescents pursue post-secondary education. Approximately 20.2 million students were expected to attend American colleges and universities in the fall of 2015 (National Center for Education Statistics, 2015). This often involves moving away from home, but does not mean adolescents stop relying on their parents for support in various areas. Adolescents over the age of 18 continue to rely on their parents for economic and emotional support (Aquilino, 2006) and adolescents may continue to benefit from parental involvement in their interactive technology use (Vaterlaus & Tulane, 2015). In their review of technology use among late adolescents (18-25 years old), Coyne, Padilla-Walker, and Howard (2013) suggest that it would be challenging to monitor adolescents' technology use when they leave for college because of proximity limitations.

Vaterlaus, Beckert, and Bird (2015) queried 82 college students (18-25 years old) and 72 parents regarding parental mediation practices in late adolescence. College students (and their parents) who lived with their parents reported low levels of parental mediation of late adolescent cell phone (7%) and internet (11%) use. Similarly, college students (and their parents) who lived away from home also reported low levels of parental mediation of cell phone (28%) and internet use

(13%). Participants who reported parental mediation of college students' technology use indicated that the same strategies (i.e., monitoring, active mediation, and restriction) that have been identified in research with younger adolescents were employed. Furthermore, Vaterlaus et al. (2015) asked participants who reported no parental mediation to explain why parental mediation was not implemented. Some parents and college students reported that parental mediation did not happen because parents lacked the technological capabilities to mediate internet or cell phone use. Parent-child trust was thought to be earned while an adolescent was in high school and the earned trust eliminated the need to implement parental mediation when the adolescent entered college. Coyne and colleagues (2013) posited that parental mediation might be conceptualized as parental control, which could be interpreted by college students as parental intrusion. The Vaterlaus et al. (2015) study focused on adolescents who pursued post-secondary education and presently it is unclear if adolescents who seek different opportunities following high school graduation have similar experiences with parental mediation.

FUTURE RESEARCH DIRECTIONS

The majority of the research on parental mediation has centered on descriptions of the different techniques parents use and fewer studies have investigated the actual influence of parental mediation on adolescents' outcomes. Future research should prioritize studies focused on evaluating the effectiveness of different parental mediation techniques in reducing negative behavioral outcomes for adolescents. If specific parental mediation techniques are found to reduce risks associated with adolescent interactive technology use, researchers should then identify ways to aid parents in overcoming the barriers to implementing parental mediation techniques. It appears that parents' limitations in technological ability serves as a barrier to implementing some of the

parental mediation techniques. Research focused on methods for increasing parents' technological abilities may be a way of decreasing the digital generation gap and increasing parental mediation. Finally, researchers and practitioners should then create, implement, and evaluate interventions and educational programs for parents and adolescents to increase the use of effective parental mediation techniques.

CONCLUSION

Interactive technology use has become an integral aspect of adolescents' lives. Parents do have concerns about adolescent interactive technology use and, because legal regulations on interactive technology are difficult to create and regulate, policy makers rely on parents to take responsibility for keeping their adolescents safe from these risks. Some parents have implemented various parental mediation strategies (i.e., active mediation, restrictive mediation, and monitoring) in an attempt to prevent negative consequences for adolescents. There remains much to be learned regarding the effectiveness of parental mediation at decreasing the potentially negative consequences and increasing the potentially positive consequences associated with adolescent interactive technology use.

KEY TERMS AND DEFINITIONS

Adolescence: The human developmental time period between childhood and adulthood.

Active Mediation: A parental mediation technique where parents use parent-child discussion and participation in their adolescents' technology use to alert adolescents to risks associated with interactive technology.

Digital Generation Gap: A difference between parents and adolescents in knowledge about how to use interactive technology.

Interactive Technology: Technology that digitally facilitates interaction between people or allows for user content creation or manipulation.

Monitoring: A parental mediation technique where parents view adolescents' activity (e.g., internet history, text messages) on interactive technology with or without the adolescents' knowledge.

Parental Mediation: Parental interventions and interactions with their adolescents regarding technology use implemented to promote positive technology use.

Restriction Mediation: A parental mediation technique where parents block access to interactive technology or implement limits (e.g., rules) on adolescents' interactive technology use.

The Qualities and Potential of Social Media

University of Winchester, UK

INTRODUCTION

Technology has long been thought to bring about change in human behavior. This varies from minor changes in individual behavior to larger societal level transformations. Twitter and a variety of other social media have been considered as playing a significant part in facilitating, if not causing, recent political revolutions in certain North Africa and Middle Eastern countries in which long standing political regimes established in the post-colonial period were overthrown often by internally driven anti-systemic movements. In a number of instances the overthrow has resulted in less stable states (Khamis & Vaughn, 2011). Similarly, social media has been credited heavily in the spread and organization of the various occupations and civic unrests that occurred in Western societies under the auspices of the Occupy movement (Gleason, 2013). Occupy is a globally distributed network of anti-systemic groups broadly opposed to what they perceive to be systems of economic inequality and the pan governmental legal instruments that facilitate such inequality. A significant volume of commentary on blogs and in newspaper columns has clearly identified social media (often accessed by a mobile phone) as one of the driving forces and key tools of these uprisings (Marzouki, 2011).

Similarly, in commentary on less headline-grabbing events, we also find social media as credited with a change causing potential and social media has also been considered as a way to improve organizational performance (Curran, O'Hara & O'Brien, 2011). In business and management so-

cial media is seen as a way to empower customers and users, improve service levels through feedback loops and generally offer an improved service users' experience of bureaucracy. In this article we examine how the qualities and potential of social media can be understood to cause social change.

BACKGROUND

Social Change

Collective human life is structured by social practices; they define accepted behavior and how we act in different circumstances. Sociologists often understand such social practices as changing and shifting in response to social dynamics, logics and developments as well as external drivers (Giddens, 1990). We may understand technology as a major agent in driving such social change though there is disagreement in the manner in which such change occurs (Leaning, 2009) and whether such change is socially beneficial. One argument is that social media are contributory to the general decline of collective action in social life - social media contribute to the atomization of society and a decline in social capital - the binding connections between individuals. An opposing position contends that social media and similar technology actually contributes to social capital since there "is clear evidence that social capital has been on the ascent in the past decade: in the form of networks in cyberspace" (Lin, 2001). That is, the interpersonal connectedness facilitated by

social media is beneficial and indeed social media afford communities opportunities to internally 'bond' or change in a positive, affirming manner.

Social Media

Social media refers to a range of World Wide Web (hereinafter referred to as 'web') applications that facilitate communication between individuals. Numerous technical sources identify the ancestry of social media in web 2.0 technology. Many of the features considered unique to social media (such as interest-driven communities, peer commentary and horizontal rather than hierarchical information flows) were present in early internet communication systems. Indeed much contemporaneous commentary on social media echoes statements made about the internet in the 1990s and early 2000s.

New Technologies

In analyzing technology we often seek to find characteristics, features or qualities that were not present in whatever technology went before – social media must do something that previous media simply did not do. The cause of this perception lies in the marketing and financing of new technologies; there has to be a unique selling proposition of a technology, it has to offer a feature that solves a problem that previous technologies did not. However, this runs counter to the way in which technology is developed. Technology does not progress in terms of major changes, it moves forwards cautiously rather than in leaps and bounds. We might argue that technological innovations occur on a continuum; new technologies slightly improve a particular aspect of what went before but they rarely take things in a new direction entirely. A new technology may do the task we want performed better but only very rarely does it perform a new task.

Moreover, we should recognize that technological history is often not a single, linear pathway (Nicholson, 2007). While from our current per-

spective a technology may seem to be the result of a continuous path of development we find that there are often many developments that leading to technological cul-de-sacs. We may see the development of technology as occurring in a similar fashion to natural evolution - many different approaches to problems are tried out, some succeed but many fail. However, the important aspect is that each instance of technology is designed as an end in itself, to solve a problem or meet a need. Technologies are not (normally) developed as a stepping-stone to a clearly defined future technology. However, when we examine technology in hindsight that is exactly what they appear to be. Technology is not consciously moving towards a specific goal, rather it is changing and transforming and fighting for survival in an environment of limited resources (Ziman & Ziman, 2003). Thus if we look at social media we find that many of the features are actually improvements upon already existing patterns of communication rather than 'true' innovations. Different forms of social media may share certain features in common and seem to be advances of earlier technologies but whether they are radically different from previous forms of technology and communication is contestable.

THE CHARACTERISTICS OF SOCIAL MEDIA

If the argument that social media do possess new characteristics is correct then we can start to identify the particular areas in which social media is an improvement on what went before. In this article we focus on four key areas:

- The contemporaneity of communications;
- Productive audiences;
- Its dialogical and network nature; and
- Its searchable and 'taggable' nature.

While these characteristics were present in previous internet enabled media (and even earlier in some cases) they are modified, adjusted and

combined in new ways in social media that allow us to see social media as a new technology.

The Contemporaneity of Communications

The contemporaneity of communications refers to the way in which social media are constant in people's lives and how they afford the user continuous routes of communication. Initial social research on internet communications articulated a divide between those technologies that afforded synchronous communications (live, real time discussions such as the various chat systems) and those which afforded asynchronous communications (turn taking systems such as new forums and email lists).

Social media confound this simple division. This occurs for two main reasons: first, many social media platforms incorporate both synchronous and asynchronous communication systems allowing users to both discuss issues in a serial manner asynchronously while also engage in synchronous communication – thus Facebook allows serial communication through status updates and comments but also to directly message a fellow user and engage in synchronous communication if they are logged in at the same time. Second, social media platforms are accessed through a range of hardware platforms including desk-bound personal computers, tablet devices and mobile devices. Accordingly social media is far more accessible and invasive into contemporary personal life than previous communications systems. While social media do not really offer anything new in terms of sheer communicative practice – they still offer an interface through which we can communicate – the means of accessing and communicating through the media is significantly advanced. Because of the penetration of computing devices into work, home and personal spaces and the presence of 'always on' 3G (and more recently 4G) mobile device networks, communication using social media is constant and 'network presence' is increased.

Using social media through 'always on' devices means that we are almost continually in communication. Communications are not stored and delivered to us on a particular occasion but relayed directly to us via social media platforms on mobile devices. Communication becomes cotemporary and we are deemed ever-present in the network.

Productive Audiences

While the amateur production of media content has long been possible through low cost media technology, social media add the dimension of being able to distribute this content easily. Many social media platforms offer the user the ability to upload media content. While there has been much concern (with considerable justification) about users disseminating commercial content without full recompense being made to the copyright owners, what is most striking is that there are significant volumes of media content produced and uploaded without any financial reward for the user/producer. This represents a marked shift from the previous conception of the relationship of media producer to audience.

In the previous older model there was a clear line between those producing media content: professionals who had undergone a period of training and development and part of a media industry – and those consuming it, the audience. Though there has been a reconsideration of the passivity of the audience of the audiences and audiences are no longer considered as passive as once thought even for old media, social media are thought to offer a new dimension of activity. In some instances these productive activities are aligned to their consumption and engagement with professionally produced content (phenomena such as fan media, parody and 'mash up' of professional media content into new content) but many people also produce their own entirely new content (Jenkins, 2006).

Dialogical and Network Nature

Social media are inherently social; they permit users to communicate with one another easily. While many forms of media allow users to communicate with other users and a significant number of pre-web 2.0 internet communication platforms are explicitly based on this, in social media this is elevated to a new level. The manner in which this occurs is through the integration of intra-user communication into other forms of association. This occurs in three main ways. First, social media allow communication between users who have engaged in content dissemination or consumption of content uploaded by others. Thus, many of the social media platforms dedicated to content dissemination such as YouTube or Flickr permit users to post comments tied to specific media texts and to 'rate' the posted texts. A consequence of this is that sustained discussions emerge around texts and often veer into new areas with links to other texts being posted. Second, social media permit communication by prior existing communities that have a presence online. Innumerable geographical, interest-based, friendship and other forms of associational groups that exist off-line also have presence in social media. Moreover these groups are extended in new ways by their being online – users are made aware of prior existing groups and are able to join them and learn of their activities easily. Third, users are in multiple networks and users function as 'nodes' between separate networks. Social media allow users to facilitate new associations and forms of sociality. A consequence of this is the emergence of new networks and groups that only exist through social media.

Searchable and 'Taggable' Nature

The 'taggable' nature of media content refers to the way in social media allows users to add descriptors or 'tags' to media content so that it becomes identifiable and findable by themselves and other users. For example, wireWAX (a taggable video startup) allows interactive media content to be

overlayed on YouTube streaming media. The benefit of the 'tagging' aspect is that the manner of description of an object stored online becomes far more personal and familiar to the individual. In this manner the user does not have to become skilled in the arcane and technical means of description. Accordingly, the labelling of content becomes far more democratic, personal, useable and epistemologically 'local' what Vander Wal refers to as 'Folksonomy' (Vander Wal, 2005). This is the opposite of technical taxonomy where a single authority determines classification: folksonomy is a bottom up approach to defining information and content. As such the practice affords strong resonance with grassroots and anti-hierarchical interpretations of the impact of new and particularly social media.

SOCIAL MEDIA CAUSING A CHANGE

We consider the above noted differences as resulting in four practices that can facilitate social change. These practices are: folksonomy, virality, collective intelligence and the emergence of 'long tail' patterns of production.

Folksonomy

As we noted above, social media allows users to add tags to digital content. Such tagging permits new realms of information to build up around digital content. Of particular interest is the impact this has upon classifications of digital content and data. As the amount of tagged data rises, it begins to pose a threat to the existing definitions and descriptions given to the data when it was first uploaded. If people add their own descriptions and do so in numbers, then the importance of the original description gradually declines.

This affords new ways in which information can be identified and found. Media theorist Dennis McQuail noted that electronic media caused a change in how information was stored, disseminated and accessed. McQuail (McQuail, 1992)

was in turn developing ideas proposed in 1986 by Bordewijk and van Kaam (Bordewijk & van Kaam, 1986). They proposed that interpersonal information transfer works in one of four ways:

- Allocation (from a central point to individuals - as in broadcasting);
- Conversation (exchange of information between peers);
- Consultation (where information is stored in a location and individuals retrieve it - as in a library system); and
- Registration (where those in the centre record information from different end points).

McQuail contends that in an age of new media the traditional model of allocation is challenged by the model of consultation. We now longer passively receive information but can go in search of it. However, as many have pointed out how data is defined, labelled and stored has a significant impact upon whether it can be retrieved. Historically data has been classified by experts in the field, such as librarians, often using complicated systems. What tagging does is allow individuals to add their own labels. The consequence of this is that expert systems of information description are challenged by one driven by non-expert users – folk – to use the colloquialism. Folksonomy is the description of information by the people who use it and the consequent challenge to the power structure of those who have historically labelled it.

Virality

If folksonomy is a challenge to those who label information, virality is often considered a challenge to those who have traditionally controlled the pathways of information flow. The idea of virality emerges from network society theory - a broadly sociological approach to understanding the density and multi-directional forms of communication present in the contemporary world. It

was developed in the work of (amongst others) Manuel Castells (Castells, 2011a, 2011b). In addition to the significant amount of academic commentary, network theory has also attracted much popular commentary. This commentary has constructed the network society in both positive and negative ways.

One ‘vision’ has been the interpretation of contemporary society as being highly integrated with individuals being part of many different communities of networks. We are part of work communities (our colleagues), family and friendship communities and geographic communities (our neighbors) and many historical communities (people in places we have lived in before or met) which social media permits us to remain in even if we leave the physical site of its original creation. Of course such links were possible in the pre-social media age and the pre-internet age. But the links are made far easier to maintain in the social media age and certain qualities of social media applications and sites such as Facebook make locating and contacting old acquaintances far easier. On top of this technologically facilitated ‘social network’, new changes such as the proliferation of platforms and platform independent content means that content can now easily flow across the network.

In previous eras, information tended to follow quite strict pathways through society. Old media forms such as newspapers and television afford a unidirectional flow of information from a central point outwards. The internet and other forms of new media challenged this in the 1990s and 2000s and social media has greatly accelerated the challenge. Information now easily crosses between social networks and it does so that patterns of flow now appear chaotic and not managed or planned. Indeed they seem to spread not with a rational, intelligent plan behind them but with a biological or chaotic pattern. This resemblance to the biological spread led to the coining of the term viral to explain the spread of a piece of film, image or other media file. The link to biological

phenomena is strengthened when the idea of virality is linked to the concept of a 'meme'. In the work of evolutionary biologist Richard Dawkins (Dawkins, 1989), a meme is a concept or idea that 'floats free' of its originating discourse and spreads with a society or culture in a similar way to how successful genes spread across populations. If specific discreet units of media are considered memes then the idea of a viral pattern of distribution becomes stronger.

Virality as a form of media distribution has proven to be a significant upset to those historically in control of media. While entertainment clips that spread virally are not considered of much consequence, virality achieves more significance when the spread information conflicts with dominant systems of representation and challenges the existing political order. In such instances virality becomes a subversive social practice that adds a political dimension to social media.

Collective Intelligence

A wiki is a type of website that allows the collaborative production of information. Possibly the best known wiki is Wikipedia. The Wikipedia website contains information that has been gathered and systematically organized in a collaborative manner by multiple users. The collective of collaboration and information sharing (which is sufficiently dynamic and also co-ordinated) over physical distance, results in properties which may be seen as 'smart' or 'intelligent'. This spawns emerging capacities beyond the individual components. Collective intelligence involves the ability to receive, transmit, utilize and share flows of information. Sociologist, Kingsley L. Dennis, argues that successful wikis (such as Wikipedia) make 'smart' decisions since they embody forms of an emerging hybridized collective intelligence – where the weaknesses of the individual are compensated by the contribution of the many.

James Surowiecki (Surowiecki, 2005) identified that in many instances collective decisions

by many non-experts produce better results than those by individual experts. For Surowiecki, crowds can be 'wise' but they also need to be diverse and beyond physical homogeneity in order to be so. Dennis suggests that there are therefore degrees of 'intelligence' to be found in collectives that are diverse, distributed and heterogeneous yet sufficiently connected to share affiliations similar to information flows. The 'new agora' that wikis offer is informed through a synchronization of material in tandem with communication and digital technologies. As Wagner (2009) notes, by using wikis and related technologies, significant insights may be drawn from many small chunks of knowledge that carry relatively little meaning individually but become exceedingly meaningful when combined.

Long Tail

The 'long tail' is a description of the way in which retailing in the contemporary world allows small businesses that produce a niche product can exist in a world of mass production. The term describes the statistical phenomenon of a chart showing frequency distribution of a low number of instances of many cases. Such a chart will detail a dataset which has a number of cases with a high number of incidences and a gradual decline in the occurrence across the rest of the cases. The chart will have a small number of cases with a high number which forms a peak on the left of the chart and a gradual decline in the occurrences to the right forming a 'long tail'.

The 'long tail' was popularized in Chris Anderson's text (Anderson, 2007) when he noted that it described a number of new internet business such as Amazon which sold a high volume of a very small number of products but a small volume of a large number of products. Anderson proposed that companies could make money by selling very little of many different products; a challenge to the traditional wisdom of retailers of selling a significant amount of a very limited stock range.

The ‘long tail’ describes how media content in the social media environment is consumed and produced. There are a number of texts that achieve high audience numbers – successful internet memes as described in the virality section above; yet there are many media texts that never achieve a large audience. What is interesting is that there are a significantly high number of these.

There are innumerable videos on YouTube with few viewers, many blogs go unread by more than a handful of readers and the vast majority of Twitter streams have only a very small number of followers. This does not lessen the importance of these media; rather it simply indicates that very different consumption patterns of social media. The ‘long tail’ is a description of contemporary consumption patterns which owe much to the impact of the characteristics of social media.

FUTURE RESEARCH DIRECTIONS

While future gazing is always a problematic and a questionable activity, we identify a number of possible trends in social media development and extrapolate from these to the future.

The Self-Leveraging Network

The rich data in networks offers marketing professionals many opportunities for targeting potential customers more intelligently. While this has been possible for a number of years through the use of algorithms that detect patterns of interaction between users and data assets and then target the user with new assets, a number of companies are now developing this approach in a more intelligent or strategic manner. For example, the start-up *Insightfully* has developed an application that takes information from a person’s Twitter and LinkedIn accounts and identifies potential relationships based upon data and previous encounters. The application (or simply ‘app’) explores the interaction between a person and their networks by calculating how much the network assists the person and

how much the person assists the network. In this way it exploits extant data in new ways delivering nuanced information that can be used to assist the person in leveraging their networks.

Deeper Personal Profiles and the Universal Identity (ID)

The social media market is currently very heterogeneous - numerous platforms abound and users maintain many different accounts on these platforms. An increasing problem for platform providers is users not completing profiles. Users often only partially complete the various steps and this has an impact upon both the value of the data (partial data is far less valuable to advertisers) to the social media company and value to the user. In addition to inaccurate information being targeted at them, partial profiles often result in far less traffic and awareness among peer communities.

During 2010, Facebook initiated *Facebook Connect* – this allowed users to use their Facebook login on third party sites. This was followed by *Open Graph API* which has now been adopted and developed by numerous other organizations. Such practices presage the advent of what we may term the Universal ID or login – a system in which we use one login to access all our personal data stored across a range of platforms and organizations. This would facilitate being able to access and straddle multiple platforms and systems without multiple login processes.

Hyper Locality

When electronic mass media emerged during the early 20th century one of the main fears was that the world would become homogenized - a mass media, largely produced in the United States of America and western Europe would dominate all aspects of culture and would eventually drive out local, traditional values. Such fears are still felt today and significant effort is placed on preserving local cultures.

However, there is a gradual trend towards the production and dissemination of localized content. It is this aspect that is predicted to grow. Indeed given the productive qualities of social media content will become increasingly local to the individual. This serves to bring the technology 'closer' to the individual; social media will serve to assist in the narration and engagement not with a distant other (as corporate and state news seeks to do) but with our everyday lives.

CONCLUSION

We have examined how the qualities and potential of social media can be understood to cause social change. It is evident that during the last few years, social media has caught the public interest in a way that few technologies have achieved. While social media can be seen as the media used to be social, it has also become a powerful force since it has shaped government elections, impacted business decisions and altered the landscape of what news is and how it is reported. Social media has indeed become part of our everyday life.

KEY TERMS AND DEFINITIONS

Collective Intelligence: The weaknesses of the individual are compensated by the contribution of the many.

Contemporaneity of Communications: Refers to the way in which social media are constantly in people's lives and how they afford the user continuous routes of communication.

Folksonomy: The description of information by the people who use it and the consequent challenge to the power structure of those who have historically labelled it.

Long Tail: A description of the way in which retailing in the contemporary world allows small

businesses that produce a niche product can exist in a world of mass production.

Social Media: Refers to a range of World Wide Web applications that facilitate communication between individuals.

‘Taggable’ Nature of Media: Refers to the way in which social media allows users to add descriptors or ‘tags’ to media content.

Virality: The tendency of information to be circulated rapidly and widely from one Internet user to another; the quality or fact of being viral.

Wiki: A unique type of website that eliminates physical distance between the reader and the producers of the information.

S

Short History of Social Networking and Its Far-Reaching Impact

Liguo Yu

Indiana University – South Bend, USA

INTRODUCTION

Social networking is a platform built with information technology that supports virtual socialization (Lenhart & Madden, 2007). Although social networking has a short history compared with the long history of human socialization, it is growing fast and its impact on our life has not yet been fully realized and understood.

For thousands of years, face-to-face socialization is the major form to build social relations (Grusec & Lytton, 2012). Communities are formed locally, economy is developed locally, education, entertainment and religious activities are all performed locally. People interact with each other through physical contact and physical communications. Virtual communication appeared with the birth of mail service (Scheele, 1970). We have been using this kind of virtual communication for hundreds of years. However, virtual communities are rarely formed with surface mail, because mail correspondence usually happens between only two people, which are not enough to form a community. Recall the saying “One person is single, two persons are couple, and three persons form a society”, we can say that a regular mail service between two people forms no virtual community.

Virtual communication, virtual social group, and virtual community become a reality with the advancement of information technology, especially internet-based technology. Social networking was first introduced about 40 years ago. In less than half a century, it has become an

important part of our lifestyle, and moreover, it is still evolving and penetrating into every aspect of our life and our society (Papacharissi, 2010). Its future impact will be profound.

This chapter describes social networking’s different perspectives. The main objective is to help readers understand the technology potential and limits of social networking, its impact and its possible future. The remaining of this chapter is organized as follows. We first describe the background knowledge, including the evolution of social networking together with its supporting technology and the latest research development in this area. Then, we analyze the major social networking services and their features. Next section describes the new business and new socialization built on top of social networking, and their impact on social relations and social dimensions. Future research directions and conclusions are presented finally.

BACKGROUND

Social networking began with the introduction of computer network (Warschauer, 2004). The early form of virtual group is the email mailing list. Email is a communication mechanism established originally on mainframe computers in 1972 (Merritt, 2012). Later, this mechanism is introduced into personal computers on the network. A simple email communication between two users might not be too much different from the traditional surface

mail communication, because it only involves two users and no social groups or social relations are formed here.

However, an email mailing list service provides an unprecedented mechanism to group users together and form virtual communities. Users do not need to meet face to face and could share their feelings, information, and ideas, remotely. With the support of email attachment, pictures, documents, and links to information or data on the Internet could be shared within the group. Although mailing list is an asynchronous communication mechanism, it is better enough to shadow the traditional mail correspondence. Despite the fact that many modern social networking services have emerged in the past ten years, email mailing list is still widely used in business, education, and some organizations. One of the most famous mailing lists is Linux Kernel Mailing List that connects Linux developers and users and forms the Linux community. This virtual community was established in 1995 and had over 14 thousand members in 2008 (Chu, 2009), and it is still actively used as the main platform for Linux community members to post announcements, ask questions, and address issues.

Besides email mailing list, there are also some other asynchronous social networking services, which include newsgroup, discussion forum, and bulletin board. These mechanisms are similar to mailing list: one user's post could be published openly online or broadcasted to the group members. Newsgroup, discussion forum, and bulletin board are usually built into a web portal or a specific web service. For example, discussion forum is an important component of distance education software (Branon & Essex, 2001). Another example is Baidu Tieba, China's largest communication platform that allows users to set up, join in, and search different discussion forums. The service is provided and supported by Baidu, China's search engine.

With the advancement of hardware technology, software applications are also improved. Due to the increase of computer network speed and personal

computer processing power, synchronous communications became possible in 1990s. Accordingly, synchronous social networking services emerged. Because synchronous communications could provide more convenient mechanisms to connect people together, more and more users switched from asynchronous communication platforms to synchronous communication platforms.

Instant messaging is one of the most popular synchronous communication methods used in late 1990s (Lewis & Fabos, 2005). It allows real time text transmission and information sharing. The most successful example of instant messaging service is Microsoft's Messenger, which was released in 1999 and widely used in 2000s. It was basically integrated with Microsoft's Windows Operating Systems and anyone with a Microsoft account can use it. In 2013, Microsoft's Messenger was merged into Skype's instant messaging system after Microsoft acquired Skype. Once, the users of Microsoft's Messenger had reached over 300 million.

Original social networking services only support text transmission. With the evolution of information technology, audio and video transmissions also became possible in the 2010s. For example, Microsoft's Sky Group Call is one of the most popular video conference services. Latest social networking services include more than text, photo, audio and video sharing. Other business and entertainment features are also incorporated. These features will be detailed in the following sections.

Research in social networking has been actively conducted in the past years. The work includes the study of communications through emails (Yu et al., 2008), mobile phones (Matic et al., 2012), instant messaging (Leskovec & Horvitz, 2008), and online social media (Kwak et al., 2010). For example, mobile communication data is used to study social network structures and social relations (Yu et al., 2013); emails are used to understand communication patterns (Malmgren et al., 2009); and social media is used to study recommendation systems (Carullo et al., 2015).

These studies revealed interesting facts about virtual relations and virtual communities (Chianese et al., 2015; Rheingold, 2000). Social networking in professional communities are also extensively studied. For example, Yu, Guan, and Ramaswamy (2016) studied the communication patterns of Linux virtual community; Russell (2013) studied the social relations of LinkedIn, Google+, and GitHub professional groups.

THE COMPETITIVE SOCIAL NETWORKING SERVICES

As with any other business domain, social networking services are evolving. Currently, a few internet giants are dominating the social networking service industry, while many others are fighting aggressively to obtain their market share. It is worth of studying the business strategy, service feature, user base, and financial status of different social networking services in order to better understand this industry.

Facebook

It is fair to say that Facebook is currently the most popular social networking platform. Facebook was launched on February 4, 2004. Its founder is Mark Zuckerberg (Kirkpatrick, 2011). The basic features of Facebook allow a user to build a profile,

connect with friends, share photos, videos or other information, and join virtual groups. According to Alexa.com, Facebook is the second most visited website worldwide, only next to Google. Although Facebook is banned in a few countries, including China, Iran, North Korea, Syria, and Cuba, there are over a billion monthly active users on Facebook platform. The impact of Facebook goes beyond our daily life. From domestic issues to international affairs, virtual communities on Facebook are playing more and more important roles. Table 1 shows the growth of Facebook in terms size, MAU (monthly active users), revenue, and net income.

Facebook is one of the most valued tech companies based on market capitalization. Other highly valued tech companies include Apple in computer hardware industry; Goggle in search engine; Amazon in e-commerce; and Microsoft in software industry. We can see that Facebook is the only high valued tech company of USA that is specialized in social networking services. Moreover, Facebook is still growing, with a 3.7% user growth rate in 2015.

Tencent

Tencent is China's internet company. Its founder is Pony Ma (Tse, E. 2015). Tencent provides many business services, such as gaming, news media, finance, sports, and entertainment. However, the

Table 1. The growth of Facebook

Year	Number of Employees	MAU (billion)	Revenue (\$ million)	Net Income (\$ million)
2008	850	0.1	271	-194
2009	1,218	0.2	777	35
2010	2,127	0.5	1,974	641
2011	3,200	0.8	3,711	1000
2012	4,619	1.0	5,089	1694
2013	6,337	1.2	7,872	1,491
2014	9,199	1.4	12,466	2,925
2015	12,691	1.6	17,928	3,669

Data source: Various web sites on the Internet

most important service provided by Tencent is social networking. Tencent's first social networking service is Qzone (QQ). Qzone was originally a PC-based instant messaging service. Later it was made available for mobile devices. Qzone is mostly used in China with over 800 million active accounts. It has become a platform for Chinese remote socialization.

The latest social networking service developed by Tencent is called WeChat, which is a pure mobile-based social media platform. WeChat is not only used in China, it is globally notable. WeChat was launched in 2011. In less than five years, it has got over 650 million users by 2015. Different from Qzone, the number of WeChat users grows fast internationally. Currently, most international users are in Southeast Asia, India, and Africa. But more and more users from America and Europe are joining in this social networking platform.

WeChat provides text messaging, voice messaging, broadcast messaging, video calls, and data sharing services. Other features include walkie talkie, group chat, shake, and friend radar. Because of its popularity, more and more users have switched from Qzone to WeChat. It is worth to note that both Qzone and WeChat have developed across the social networking domain. They have become platforms for ecommerce, gaming, and financial transactions.

Tencent is the most valued tech company in China. Domestically, it is competing with Alibaba on various internet-based services, such as online payment, online taxi-dispatch, music, sport, and entertainment. Globally, it is competing with Facebook on social networking services.

Twitter, Sina Weibo, Tumblr, and Others

Twitter is a social networking service that enables users to broadcast short messages to their followers. It was launched in 2006 and went public in 2014. Twitter is currently the most popular micro blogging service worldwide. Twitter has a limit on the size of the text message and usually only text could be sent. Image, audio, video, or other data formats are not supported.

Sina Weibo is mainly China's microblogging service. Like Twitter, users of Sina Weibo could choose to post messages publicly or broadcast messages only to their followers. Tumblr is Yahoo's social networking service. Similar to Sina Weibo, Tumblr users could post images, audio or video files.

Table 2 compares Twitter, Sina Weibo, and Tumblr. It should be noted here that Tumblr is still a private company. No revenue data and net income data are available to the public.

Besides Facebook, Tencent, Twitter, Sina Weibo, and Tumblr, there are also many other social networking services. The commonly used ones include LinkedIn for business and professional networking, Renren (China) for campus networking, Habbo for teenagers socialization, and VK (Vkontakte) used mainly in Europe.

From Desktop to Mobile

The latest trend in social networking service is that the platform is shifting from desktop computers to mobile devices. Some pure mobile-based

Table 2. Comparisons of Twitter, Sina Weibo, and Tumblr

	Twitter	Sina Weibo	Tumblr
Number of Employee	3,639	2,915	368
Monthly Active Users	305 million	236 million	226 million
Revenue	1,403 million (2014)	\$477.9 million	na
Net income	-\$578 million (2014)	\$34.7 million	na

Data source: Various websites on the Internet

apps were developed and launched recently. In a short period of time, these apps have attracted the majority of social networking users.

Instagram is an online mobile photo-sharing, video-sharing, and social networking service that enables users to take pictures and videos, and share them either publicly or privately on the app (Holmes, 2015). Instagram was launched in 2010 and acquired by Facebook in 2012. It has over 400 million users in 2015.

Momo is China's another widely used mobile social networking app. It is location-based and allows users to chat with nearby friends and strangers. Momo's main feature different from WeChat is stranger socialization. For example, users could use Momo to look for lost pets, find new friends in a new area, and form a travel group on site. Momo currently has over 80 million monthly active users. It is worth to note that Alibaba, China's internet giant, is one of Momo's major shareholders. With the support of Alibaba's e-commerce, Momo has successfully commercialized its social networking services.

Snapchat is a mobile video messaging app. Its users could set a time limit for how long recipients can view their snaps (photos or videos). After time out, snaps will be deleted from the server. Snapchat is mainly used by teenagers. By 2015, Snapchat has over 200 million active users. Currently, Snapchat is still a private company and its major investors include Yahoo, Alibaba, and Tencent.

Alibaba's first mobile social networking service, Laiwang, is proved to be unsuccessful, because it lost the battle with Tencent's WeChat in China. However, Alibaba did not give up its dream of social networking services. Besides investing in emerging social networking services,

such as Momo and Snapchat, lately, Alibaba has upgraded its mobile payment system, Alipay app with a social networking feature. Although it is hard to evaluate this business decision now, it is worth to note that due to the large user base of Alipay (400 registered users, 270 active monthly users), Alibaba's new effort of providing social networking service could be proved successful.

Besides aforementioned mobile social networking apps, there are also many others, including Vines, Foursquare, Pinterest, Spotify, Hootsuite, and more. For social networking services that are supported by both desktop computers and mobile devices, Table 3 summarizes the distribution of their users on these two platforms. For other social networking services not listed in Table 3, they have close to 100% mobile users. It is clear to see that mobile devices have almost completely replaced desktop computers for socialization. Because of the shift of user preference, companies are also adjusting their business strategies. For example, it is reported that Tencent has dropped Qzone's Windows 10 development. Instead, Qzone's new development will be focused on mobile devices.

ECONOMIC AND SOCIAL IMPACT

Social networking is a business. Making profit is the goal of most social networking services. Currently, both Facebook and Tencent have successfully commercialized their services. Online advertisement is the major source of revenue. Collecting membership fees is another way to monetize virtual social relations. In addition, social networking reduces the cost of some business operations, such as marketing and payment

Table 3. Distribution of desktop users and mobile users of the popular social networking services

	Facebook	QZone	Weibo	Tumblr	LinkedIn
Desktop	32%	26%	15%	46%	26%
Mobile	68%	74%	85%	54%	74%

Data source: Various websites on the Internet

transactions. New e-commerce models have emerged on social networking platforms. Two of these e-commerce models are micro business and ceWebrity business.

Micro business could be built on top of Facebook or WeChat platforms, where a user could sell products or services to his/her friends on the contact list. Products/services information could be posted online or could be broadcasted to friends. This kind of business model certainly reduces the cost of marketing. In addition, micro business could grow fast if the user's friends are willing to share the advertisement with their friends and their social groups, and so on and so forth. Micro business is rather common on WeChat platform, partly because Tencent's payment system is integrated into WeChat, which simplifies the payment transactions.

CeWebrity business could be built on top of Twitter or Sina Weibo platforms. This business is mainly operated or marketed by a celebrity on the Web, who could have thousands or millions of followers. The products or services are usually sold to the followers of the celebrity through broadcasting advertisement on social networking platforms. Because Twitter has a text size limit and does not support photo or video sharing, currently, it is not ideal for ceWebrity business. However, ceWebrity business grows fast on Sina Weibo's platform. Another common platform for ceWebrity business is YouTube. Celebrities on the Internet could post their products or services information on YouTube to make them available to the public, and especially to their subscribers. In this sense, YouTube is also a social networking platform similar to Instagram.

The effect of social networking goes beyond business. It affects every aspect of our life, including education, healthcare, entertainment, and more. Various new social groups and social relations are built on social networking platforms. Members in the virtual community can share their feelings, ideas, and experiences. They could also seek helps and advices from other community members. Users could play together, work to-

gether, and shop together. Using entertainment as an example, social networking has been used as a platform for live music shows. Moreover, other apps could be integrated into social networking apps, making it more convenient for social networking users to do different things, such as booking a ticket or paying utility bills.

Social networking not only broadens the horizon of our social relations, but also provides us better opportunities to develop mutual understandings in various social dimensions. Cross border and cross cultural relations could be easily developed with social networking. Through interacting with people of different cultures and different belief, we could better value other's living system and lifestyle. Social networking provides a cost-effective way to foster the respect of diversities. The traditional social dimension development is achieved through reading books, watching TVs/movies, browsing the internet, traveling, joining clubs, and participating in various events. Social networking provides additional mechanisms for social dimension development. It enables us to join remote cultural groups and form remote cross-cultural relations easily, allowing us to live in a virtually diverse environment. Therefore, in general social networking has a positive influence on individual's development of universal ethical principles, which are essential for us to resolve social and cultural conflicts and reduce social and cultural inequalities.

With the expansion of social networking services, people are joining in more and more virtual groups and spend more time on virtual socialization. For example, there are over 600 million groups on Facebook. Both Facebook, Qzone, and WeChat allow users to setup their own groups. Latest data shows that Facebook users spend twenty more minutes on it a day and China's WeChat users spend more than forty minutes on it a day. These numbers are expected to grow as people depend more and more on social networking. The latest development in this area shows that different social networking services are trying to connect their services together in order to

build more communities and larger communities. For example, WeChat has been integrated with LinkedIn, allowing WeChat users to invite their LinkedIn contacts to join WeChat.

FUTURE RESEARCH DIRECTIONS

It is reasonable to say that we are living in two worlds now, a real world through which we interact and communicate with others physically, and a virtual world which is built on top of social networking. In our virtual world, we interact and communicate with others remotely. Technology has helped us build this virtual world, and it will continue to improve our experience of virtual socialization. The technologies that are under development and might have great potential to enhance social networking services include VR (Virtual Reality), IoT (Internet of Things), and SE (Smart Environment).

VR (Virtual Reality) is the emerging technology that can simulate the physical environment and bring close-to-real experience for the users. For example, with the help of physical devices, such as special screens, head phones, and sensory devices, users could feel existing in a different environment like real. IoT (Internet of Things) is the network to connect all physical objects online, which also means these objects can be controlled remotely by users. With this technology, physically separated users are connected more closely, which allows physical interactions through remote objects. SE (Smart Environment) is the idea to build an environment with embedded sensors, displays, and computing devices. The main purpose of SE (Smart Environment) is to seamlessly merge human being into the environment, making us easy to feel, understand, and control the environment.

VR, IoT, and SE are closely related when they are going to be utilized in social networking. Although these technologies are still on their early stages of development, they are believed to be part of the driving forces for next economic boom. Once these technologies are matured and incorporated

into social networking services, the impact could be revolutionary. Potential applications include gaming, virtual sport, entertainment, and more. Technology and internet giants, like Microsoft, Google, Facebook, Tencent, and Alibaba, are all actively investing in these technologies.

CONCLUSION

In this chapter, we discussed the evolution of social networking together with its supporting technology. We also described the most popular social networking services, their features, and their business status. The new business and new social relations that are built on social networking platforms are described. The economic and social impact and future potentials of social networking development are also illustrated.

Now days, technology is an integral part of our daily life. We are utilizing technology, and at the same time technology is affecting our lifestyle. Social networking is a perfect example showing how human activities and human society are affected by technology.

We are living in a changing world and changing society: the borders between countries are disappearing and the distance between people is shortening. The world is getting smaller. As for the future, we really do not know how it will look like. But, we can imagine. With the advancements of technologies, our imagination could become real.

KEY TERMS AND DEFINITIONS

Asynchronous Communications: A communication mechanism that does not require the sender and the receiver to be online at the same time. A delay of response is allowed and expected for this kind of communication.

Celebrity on the Web: Someone who is famous on the Internet.

CeWebrrity Business: An e-commerce business operated and/or marketed by a celebrity on the Web. The products or services are usually sold to the followers of the celebrity through social networking.

Desktop Computers: A personal computer that is mainly used in a single location. Two representative desktop computers are IBM PC and Apple Mac.

Internet of Things: A technology that connects physical objects online so that users can control these objects remotely.

MAU (Monthly Active Users): A social networking service metric that counts the number of users who perform at least one activity (sending a message or reading a message) on the platform in one month period of time.

Micro Business: An e-commerce business built on top of social networking services, in most cases, mobile social networking services, where a store owner sells products/services to his/her friends in the app's contact list.

Mobile Devices: Smartphone and tablet computers that could be carried and used anywhere. Usually wireless network is needed for mobile devices to be connected to the Internet.

Smart Environment: The idea to build an environment with embedded sensors, displays, and computing devices so that users can better understand and control the environment.

Social Networking: A service based on internet technology that allows users to communicate and socialize remotely.

Synchronous Communications: A communication mechanism that requires the sender and the receiver to be online at the same time. An immediate response is expected for this kind of communication.

Virtual Community: A group formed on top of a social networking service. In most cases, group members have the same interest but are remotely located.

Virtual Reality: A technology that can bring close-to-real physical experience for the user.

Virtual Socialization: People socialize through using computer-based technology. No face-to-face interactions and communications are needed.

INTRODUCTION

In today's competitive environment, businesses are continuously exploring ways by which customers can be better engaged to sustain long-term growth (Aral, Dellarocas, & Godes, 2013). Because of the unpredictable and wide dispersion of social media (SM) platforms, businesses today face many challenges that did not exist a few years ago (Dong & Wu, 2015). SM platforms are economical and user-friendly and facilitate the consumption, generation, and sharing of user-generated content by the consumers (Sigala & Marinidis, 2009). As most of their targeted customers are present on various SM platforms, businesses are aligning their strategies and tactics to incorporate these platforms at all levels. This shift toward SM platforms can be determined by several factors including declining response rates vis-a-vis traditional customer engagement methods, technology development through customer participation, open communication of customer preferences, low cost of information dissemination, and the demographic shifts toward use of new technologies (Gillin, 2007).

SM platforms offer an easier and more cost-effective way for businesses to reach customers, and consequently strengthen brand awareness through numerous applications and tools (Rodriguez-Donaire, 2012). Using SM platforms, businesses can define or re-define relationships with both new and old users, respectively, and develop communities that interactively collaborate to identify issues and solutions for both themselves and businesses (Meredith & O'Donnell, 2011). Businesses appear to believe that such SM initiatives are justified

because of their potential to generate profits, for instance, through advertising (Aral et al., 2013). Businesses can improve branding and direct more traffic to its web site utilizing SM advertising.

Furthermore, customers can add value by generating their own content to influence the purchase decisions of others through peer-to-peer communications. SM platforms enhance the communication power of individuals by providing different avenues without demanding much effort of the users (Curran & Lennon, 2011). Apart from creating and sharing knowledge, users can create or join various communities with other like-minded individuals based on their similarities of interest and purpose. Also referred to as virtual communities, they help users create personal relationships in an enabling environment through emotion-laden discussions (Rheingold, 2000). These communities have resulted in new opportunities for businesses (Brodie, Hollebeek, Juri, & Ili, 2011). Some of the activities undertaken by businesses include sharing of content, interaction with customers, gathering customer feedback, provision of customer services, and effective collaboration with employees or business partners, and so on. (Bowden, 2009). Furthermore, SM has not only strengthened the existing relationship between businesses and users but also resulted in innovative changes in traditional communication methods, thereby enhancing the capability of businesses to better interact and dialog with users.

In light of above, this chapter attempts to explain SM in greater detail and as delineated by various business practices. This understanding of the use of SM by businesses is preceded by

a discussion on the definition of SM platforms, their different types, and the associated business models.

BACKGROUND

Social Media

The definition of SM has been evolving over a period of time. According to Terry (2009), it refers to “digital technologies emphasizing user-generated content or interaction” (p. 508). User-generated content supported through SM is “a mixture of fact and opinion, impression and sentiment, founded and unfounded titbits, experiences, and even rumor” (Blackshaw & Nazzaro, 2006: 4). The content available on these SM platforms consists of various pieces of online information which are generated and shared by users about brands, products, and services. Often SM is referred to by its channel characteristics, either identifying directionality of messages (Kent, 2013) or using particular tools such as Facebook or Twitter for engagement and communication (Howard & Parks, 2012).

Although there is a lack of a formal and concise definition, SM is often defined as Internet-based applications that transmit user-generated content. Some definitions are simply based on the nature of communication in SM. For instance, Russo, Watkins, Kelly, and Chan (2008: 22) explain SM as “those that facilitate online communication, networking, and/or collaboration.” Kaplan and Haenlein (2010: 61) offer a similarly definition of SM as “a group of Internet based applications that build on the ideological and technological foundations of Web 2.0, and that allow the creation and exchange of User Generated Content.” In the same manner, Lewis (2009: 2) noted that SM simply serves as a “label for digital technologies that allow people to connect, interact, produce, and share content.”

In addition, Aula (2010: 43) defines SM as a place where customers can communicate directly

with their favorite organizations and gather more information about the organizations’ products instead of simply providing a platform for individuals to stay in touch with their family and friends.

These definitions could easily be applied to other communication technologies, such as e-mail, thereby missing the unique technological character that distinguishes SM.

Furthermore, a more extended and complex definition of SM is as follows:

(a) the information infrastructure and tools used to produce and distribute content; (b) the content that takes the digital form of personal messages, news, ideas, and cultural products; and (c) the people, organizations, and industries that produce and consume digital content (Howard and Parks, 2012: 362).

Kent (2010: 645) broadly defined SM as

any interactive communication channel that allows for two-way interaction and feedback, further by their potential for real-time interaction, reduced anonymity, a sense of propinquity, short response times, and the ability to “time shift,” or engage the social network whenever it suits each particular member.

The definitions become broader by combining SM and social network sites (SNSs). Boyd and Ellison (2007: 211) seminally defined SNSs as

web-based services that allow individuals to (1) construct a public or semi-public profile within a bounded system, (2) articulate a list of other users with whom they share a connection, and (3) view and traverse their list of connections and those made by others within the system.

The social network is “one of the most typical features of social media in addition to the content aspect” (Enders, Hungenberg, Denker, & Mauch, 2008: 200).

SM allows individuals to meet strangers, but rather they enable users to articulate and make visible their social networks. It also allows users to “enhance their profiles by adding multimedia content or modifying the look and feel of their profiles” (Hanna, Rohm, & Crittenden, 2011: 266).

As discussed, definitions in earlier literature, SM have been defined by specific features, minimizing their unique communicative properties. To sum up all definitions, a new definition of SM given by Carr and Hayes (2015: 50) is as follows:

SM are Internet-based channels that allow users to opportunistically interact and selectively self-present, either in real-time or asynchronously, with both broad and narrow audiences who derive value from user-generated content and the perception of interaction with others.

As observed above, the definitions are diverse and continuously evolving. This chapter will use SM platform as an inclusive term and in an operational sense.

SM Platforms

SM platforms can be differentiated on the basis of technology, content, and functions. They represent different online sources: review website, blogs, discussion boards, chat rooms, and social networking sites, for creating and sharing of information and knowledge about businesses and their products/services (Blackshaw & Nazzaro, 2006). Kietzmann, Hermkens, McCarthy, and Silvestre (2011) identify seven fundamental building blocks in understanding SM in what has come to be known as the honeycomb model: *identity*—the extent to which customers choose to reveal their identities; *presence*—the extent to which customers know whether others are available; *relationships*—the extent to which customers relate to each other; *conversations*—the extent to which customers communicate with each other; *groups*—the extent to which customers are ordered or form communi-

ties; *reputations*—the extent to which customers know the social standing and content of others; and *sharing*—the extent to which customers exchange, distribute, and receive content. Irrespective of the name of the SM platforms, one can differentiate them on the basis of these functional blocks.

SM platforms can be categorized into the following types (Lietsala & Sirkkunen, 2008): SNSs (LinkedIn, Facebook, MySpace), collaborative productions (Wikipedia), content creation and publishing (blogs, v-blogs, podcasts), content sharing (Flickr, YouTube), virtual worlds (FarmVille, Second Life), add-ons (Slide, Friends for Sale), and social commerce (Tripadvisor, Groupon, and Facebook Connect).

The number of SM platforms’ users, worldwide, is continuously increasing at a phenomenal rate. It is predicted that in 2016 there will be around 2.13 billion SM users around the globe, up from 1.79 billion in 2014. Almost two-thirds (64%) of these users use or will use such SM platforms at least once a day through their computers. However, users are now increasingly using their smart phones to access SM platforms (Nielsen, 2014). Almost 47% of smart phone owners visit SM platforms every day. Furthermore, they are logging their presence with their profiles and connecting on to multiple SM platforms. While Facebook remains the largest SM platform, users are now taking to other social platforms such as LinkedIn, Pinterest, and Instagram.

REVENUE MODELS OF SM

SM platforms were thriving primarily on user-generated content and did not focus much on revenue generation in the early phases of their growth. With the increase in the number of SM platforms with hyper-specialized focus, the modes of revenue generation are also evolving. In literature, the most discussed revenue models are advertising models and subscription models (Enders et al., 2008; Vukanovic, 2011; Wang, Ye,

Zhang, & Nguyen, 2005). The other models are: licensing of content and technology to third parties, selling goods and services to the community, and voluntary donations (Canzer, 2006; Lietsala & Sirkkunen, 2008; Zeng & Reinartz, 2003).

Advertising-Based Models

Advertising in SM platforms is now an approach that is as commonly adopted by businesses as advertising in traditional media such as newspapers and magazines. SM platforms have begun to incorporate brand pages, ad videos, and additional user-generated content for revenue. In addition, users and businesses can create their own profiles or brand sites using SM platform to advertise their particular products or services. On SM platforms, two types of advertising can be observed: affiliate models and banner advertising. In banner advertising, fees are charged by the platforms in exchange for the display of advertisements on their websites (Canzer, 2006). Facebook and YouTube are well-known examples of banner advertising. In affiliate models, SM platforms direct traffic to an “affiliate” website and, in turn, might get a percentage of revenues from the resulting sales. The popular Japanese social networking site Mixi allows users to rate and review books, games, and other items and connects users directly to Amazon Japan with one click to facilitate the purchase of those items or to listen to music which can later be bought from the iTunes store. Facebook, for example, offers businesses the option to construct individual groups in return for a sponsorship. For SM platforms relying on an advertising model, it is essential that the intended audience be large and highly differentiated to increase revenues. Thus, the key revenue driver for this model is the number of users.

Subscription-Based Model

Some SM platforms charge users for accessing content which is generated on their site. This

model requires users to subscribe by paying a specified amount for accessing content (Enders et al., 2008) on the platform. In some practices, this is referred to as the Freemium model, in which users have two choices, either to subscribe to a basic free account package which guarantees a limited amount of content/services or a pro account, at an additional cost, that provides enhanced features. For example, LinkedIn initially offers free subscription only for limited features, but for advanced features a subscription fee is charged. Sometimes users are not willing to pay a subscription fee for a service just because of a lack of trust. A certain degree of user trust is needed because users need to be convinced for them to be willing to pay for a service (Wang et al., 2005). For that, SM platforms provide free trials for users to comprehend the service offering. A good example of a subscription-based model is The Auteurs, an SM platform built around classic films. Users need to subscribe for accessing movies. The crucial driver in subscription-based models is the creation of high levels of unique customer value, which then determines their willingness to pay for a service. The attractiveness of content becomes a significant factor when companies want to charge their customers for what is essentially free content.

Another model similar to subscription model is Pay-per-item model where users need to pay SM platforms for accessing particular content of interest to them. For example, iStockphoto offers audio, video, and photos from its user stock and charges a fixed amount for each. Such SM platforms could recommend or sell user-generated content as part of their own stock on a pay-per-item terms. YouTube, another example, sells videos as per a pay-per-item model. Users need to pay a particular amount mentioned in the video itself.

The platforms either serve as a host wherein users upload their content as in YouTube and Flickr or provide additional features for the additional fees as in LinkedIn. In both the cases, user-generated content is key.

Licensing of Content and Technology to Third Parties

Licensing content to third parties may also be a source of revenue because of the tremendous growth in user-generated content on SM. An SM platform can be licensed to other businesses who want to employ similar features or services for their individual use. Twitter, for example, gains more than 15% of its sales, that is, around \$47.5 million through such arrangements. It is generated by the licensing of its massive quantity of data to analytics businesses. Although this model is not as popular and profitable as advertising and subscription, it has the potential to grow into a huge revenue stream for Twitter. Sometimes it contains provision for the licensing of content on a revenue sharing basis between itself and content generators. YouTube, for example, primarily compensates the content creators through a program called Content License Agreement, and through revenue sharing arrangement a certain amount of money is made from some videos by both YouTube and the content creator.

Voluntary Donations

In this type of model, SM platforms can use the freely available user-generated content, like that of small girl singing on the street or musician performing, for donation from others. For this, a significant number of SM platforms such as blogs, wikis, online video, and online music users ask for donations using a donate-button available on these platforms for various purposes including content access, platform maintenance, and web hosting (Goh, Heng, & Lin, 2013). This facilitates web development such as open source and user-driven innovations. For example, Wikipedia gets moneys from donations from users and other individuals. Every year, there are banners asking users to donate some money to the Wikimedia Foundation, the non-profit organization which runs Wikipedia. A common feature of such SM platforms is that they run their operations with

limited funding (often thanks to pro-bono time invested by volunteers and users).

Selling Goods and Services to Community

SM platforms have large audiences because of their networking and community mobilization capabilities and this creates an opportunity for businesses to promote and sell products or services directly to these users. SM platforms incorporate gaming techniques on their networks, driven by the monetary opportunities that they present. The sale of virtual goods will remain the primary source of revenue for these platforms. Some SM platforms, for example, allow the sale of online virtual games and virtual accessories to their users. For instance, the Mypurchase service of MySpace offers a platform to creators to sell their music, taking a portion of sales revenues in exchange.

To summarize, these revenue/business models used by SM are very new approaches, and more empirical research is required to optimize these model for better returns. Many SM platforms are now trying to integrate various revenue models to maximize revenues. For example, SoundCloud, an audio sharing platform, uses a combination of subscriptions, selling goods, and revenue sharing models. Furthermore, businesses are trying to integrate SM platforms into their activities. In the next section, use of SM platforms for various business functions is described.

SM PLATFORMS IN BUSINESSES

Many businesses use SM platforms as an advertising channel only because they are accessed by the public at large. Hence, the most evident application of SM platforms in business is to use them for different kinds of online promotional activities (Mangold & Faulds, 2009). Mangold and Faulds (2009) stated that SM platforms are an opportunity to construct brands, exhibit leadership behaviors, enlarge resources, achieve new audiences, and

find new sources of ideas. Direction (2011) proposed a collective benchmark for businesses by classifying whether they can gain benefits from SM platforms or not after incorporating them into their business functions. An essential set of related questions is how businesses should engage and communicate with customers through SM platforms (Jussila, Karkkainen, & Leino, 2011). Andriole et al. (2010) enumerated six latent factors that are influenced using SM platforms, and that ultimately affect business performance: (1) collaboration and communication: capacity to coordinate discussions, to audit communication streams, and to reach more people faster; (2) rapid application development: capacity to engage experts, customers, suppliers, and company employees to modify and to develop applications easier and faster; (3) customer relationship management: solving customer service issues, using forums, wikis, and others, mine customer data effectively, ask for customer feedback, reach more customers, and communicate effectively with customers; (4) innovation: exchange of ideas between experts, fuelled by user-generated content and mass co-creation, capability to improve success rates, to produce efficiently; and (v) knowledge management: capabilities to share, retrieve, organize, and leverage knowledge. Some researches (Bruhn, Schoenmueller, & Scheafer, 2012; Hoffman & Fodor, 2010) show that businesses have already employed SM platforms for value proposition by incorporating it into their various business activities including marketing, recruiting, product innovation, and customer service. Needless to say, SM platforms will not become effective until they are used creatively, with a systematic approach and day-to-day effort toward building confidence in the brand and a loyal user community.

Customer Engagement

Brodie et al. (2011) defined *customer engagement* as “a psychological state that occurs by virtue of interactive, co-creative customer experiences with a business.” Because of these inherent interactive

characteristics, SM platforms may connect customers and businesses by facilitating conversation and providing user-generated content, thus fostering customer engagement. In addition to this, customers who actively participate in online activities on SM platforms are regarded as highly valuable for a business. This provides benefits in terms of customer commitment, trust, customers’ emotional connect, and loyalty (Brodie, Ilic, Juric, & Hollebeek, 2013). SM enables customers as well as non-customers to contribute in marketing mix decisions and value adding (Sashi, 2012). User-generated content from SM platforms can significantly improve customer loyalty and satisfaction, particularly as customer requirements transform over a period of time (Lorenzo-Romero, Constantinides, & Brünink, 2014).

Max Bupa¹, India’s premier health insurance company, uses its engagement platform, Get Help, on Facebook to provide services to customers daily. This innovative platform enables customers to buy a health policy using their Facebook account, interact and share their experience with Max Bupa, and also get instant customer service at their convenience, anywhere, anytime. This has resulted in an increase in positive conversations with complaints decreasing by more than 60%. The turnaround time has consequently decreased by 50%.

Brand Awareness

The brand is a symbol, feature, or any other observable mark of a product or company that differentiates it from others. They are markers of recognition and composite social phenomena (Schau, Muñiz, & Arnould, 2009). Nowadays, branding is considered as an ongoing social process (Fueller, Schroll, Dennhardt, & Hutter, 2012). The social character of brands and the significance of engagement in co-creating brand value (Fueller et al., 2012) reinforce the role of SM platform as a brand awareness channel. The participatory potential of SM enables the users to affect brands in multiple ways. The recent

researches might not focus on brand reputation but on related concepts such as customer trust, emotional appeal, and brand attitude and they are showing positive effects overall (Van Noort & Willemsen, 2011). Brand reputation is a measure of how users feel about, talk about, and act toward an organization's brand (Tsimonis & Dimitriadis, 2014). Users are more likely to choose businesses with a positive brand reputation and are willing to pay more for their products. Applying SM strategies for branding can definitely help businesses. To attract more consumers, businesses are constructing their presence on SM platforms after receiving in-depth information on where and how they or their brands are positioned on SM platforms (Hutton & Fosdick, 2011). Furthermore, it is found that users' online purchasing decision is dependent on the brand perception while using the SM (Chen & Xie, 2008). The online reviews serve as critical approach in measuring brand sentiment (Stelzner, 2012).

For example, India International Jewellery Week (IIJW), an initiative to showcase India's finest jewellery, has built awareness through SM platforms as the biggest international jewellery festival in India. Various communication strategies are adopted to create brand awareness for IIJW on SM platforms. IIJW-related images and coverage of live events are uploaded on Facebook. The use of hashtags like #IIJW and tagging the celebrities are also used for promoting the event. As a result, 1166 people saw IIJW live online and its Twitter followers increased by 50% in a span of 5 days. In addition to this, #IIJW was used by 581 users and about 6,98,920 people were reached through Twitter which accounts for 1,454,957 impressions.

Marketing

Marketing is defined as an effort to find the requirements of specific communities and delivering the desired service/product to them. Earlier businesses used various conventional marketing approaches to identify such communities and assess their requirements. Today, exclusive dependency on

traditional media for marketing is inadequate for businesses to survive. In addition to creating online presence, businesses need to know how to interact with their customers online. SM platforms provide opportunities to expand relationships between users and businesses (Hlavinka & Sullivan, 2011; Lipsman, Mudd, Rich, & Bruich, 2012; Mangold & Faulds, 2009). Chi (2011: 46) defines SM marketing as a "connection between brands and consumers, offering a personal channel and currency for user centred networking and social interaction." Many studies define SM platforms as a new marketing tool (Berinato & Clark, 2010; Paquette, 2013) and appropriate for awareness building, influence, and the attainment of marketing objectives that help improve marketing communication effectiveness and make for better marketing impact (Lipsman et al., 2012). Kumar, Bhaskaran, Mirchandani, and Shah (2013) hailed SM marketing as a customer-loyalty-building and promotional tool. As supported by available literature, if SM platforms are used effectively, brand advocates can be controlled and exploited which would result in both strategic and operational benefits (Chan & Guillet, 2011).

For example, Fork You Too, a casual dining cafe in Delhi NCR, decided to go to SM platforms for restaurant marketing campaigns. They created a campaign around Bollywood movie posters with a Fork You Too-style twist on Facebook, Twitter, and Instagram. The content was strictly aligned toward food, drinks, cuisine, and events with a quirky and fun factor. As a result, Fork You Too has a fan base of more than 25,000 which increased their fan base 12 times on Facebook. They have 200 plus followers on Twitter and 250 plus followers on Instagram.

Product Design and Development

Product design and development is defined as a process which starts with identifying customer requirements and ends with converting these into a product. Customers often share their thoughts and feeling on product or event through SM platforms.

Hence, SM platforms have empowered customers to circulate their creations and opinions and thus add new content. It has also become a new method for businesses to collect people's opinions and understand their preference. User-generated content may embed customers' experiences of a product, with information on product engagement (e.g., product features) and other related information (e.g., shopping experiences; Chua & Banerjee, 2013). The strategic use of SM platforms for developing product features and form user-generated content is a comparatively new area that connects marketing and product design and is a fine example of how two formerly distinct business functions are brought together by the advent of SM (Ng, 2013).

Starbucks, a coffee house, has demonstrated its versatility in engaging customers through various SM platforms, such as MyStarbucksIdea, Facebook, Twitter, and Foursquare (Gallaughier & Ransbotham, 2010). Starbucks closely followed the principle of "design with customers" in defining the role of customers, allowing them to play the role of creators and evaluators of ideas. As a result, Starbucks received more than 120,000 product ideas, 41,000 experience ideas, and 24,000 involvement ideas all posted on MyStarbucksIdea. Starbucks has more than 36 million likes on the Starbucks corporate page and has more than 180,000 users talking about it. Seventeen million users have visited this page on Facebook. It has 18,7000 tweets on its corporate blog with 5.95 million followers following and focusing on the Starbucks' brand on Twitter, and more than 40 million followers on Foursquare.

Sales

From the sales/business function perspective, previous studies have shown that direct communication between customers and suppliers is essential in capturing the expectations with regard to a product or service and the desired requirements (Moncrief, Marshall, & Rudd, 2015). Marshall, Moncrief, Rudd, and Lee (2012) argue that the

SM platforms provide the required information to customers and share strong evidence to support the positive linkages between use of SM platforms and business success. Furthermore, it is evident that online reviews on SM platforms positively influence product sales. The prevailing positive and negative sentiments emerging out of online conversations have a significant impact on sales (Sonnier, McAlister, & Rutz, 2011; Tirunillai & Tellis, 2012). Businesses need to embrace SM platforms and related technology strategies in sales for gaining a competitive advantage (Stockdale, Ahmed, & Scheepers, 2012).

LuLu Mall, one of the most happening malls in the state of Kerala, India, launched an NRI Shopping Festival to attract NRIs, tourists, and the general public to the mall during its promotion period. The main tool used for this purpose was SM platforms to create a buzz around the events and to reach out to potential shoppers. The Facebook page and Twitter handle were updated with these promotional posts on a daily basis. The promotional content was posted on Facebook page of LuLu hypermarket, Dubai. This page had more than 40,247 fans from the Indian subcontinent including Kerala. As a result, LuLu mall increased its sales by 29%. There was also a growth in the number of Facebook likes and fans: 1,51,164 likes to 1,77,268, an increase of 26,104, with reach among fans of 53,99,573 and an impression of 86,83,222.

Promotion

A promotional approach often refers to direct marketing, advertising, and interactive marketing to encourage their products/services (Thackeray, Neiger, Hanson, & McKenzie, 2008). With the arrival of advanced technologies on SM platforms, there is an enhanced potential for promotion by businesses (O'Reilly, 2005). In the case of social promotion, this information is about product-related behaviors, ideas, and services (Thackeray et al., 2008). Mayzlin (2006) examined user-generated content which is a combination of

business promotions and user recommendations using analytical models and found that it can still be influential despite the obvious promotional aim by businesses in such online settings.

MindShift Interactive, a leading digital marketing and research firm, completed a comprehensive SM campaign for HomeShop18's new "Shopping Makes Me Happy" jingle. The promotional campaign was built on Twitter revolving around happiness and excitement among key opinion leaders with influencers exchanging tweets with reasons/people that made them happy. As a result of this, HomeShop18 surprised people with vouchers to increase the happiness quotient. This garnered an overall outreach of 23 million users across SM, trending for more than 24 hours across India.

FUTURE RESEARCH DIRECTIONS

Aral et al (2013) highlighted four major areas of research: design and features, strategy and tactics, management and organization, and measurement and value from the perspective of three levels of analysis—users and society, platforms and intermediaries, and firms and industries. Although some of the above-identified gaps are being explored, the area of research-related SM platforms is still largely unexplored. There is also a need for research in terms of differences between information-rich and information-poor countries. Many businesses are located in the developing world and are targeting customers from both domestic and foreign markets and whose use of SM platforms is different. There is a need for research specifically focusing on businesses' adoption of SM platforms in the information-poor contexts of the developing world.

SM platforms are also breeding ground for negative sentiments vis-a-vis products. An impulsive customer can damage the brand despite it being his or her own mistake. Given the dynamic nature of SM platforms, the risk mitigation strategies need to be robust and implementable. The

other challenges involved include the lack of control over the content on the platforms owned by others and the control over users in terms of access and nature of content to be viewed. There is a need for research in the creation of risk mitigation frameworks based on empirical data available.

Further research is also required for developing methodological solutions to deal with the representativeness of the SM data. As the user-generated content is limited only to the users on the SM platforms, this might not be identical to the overall population. Because not all the SM platforms share the background information about the users, generalized validation of SM data for the populations needs to be strengthened.

CONCLUSION

SM is increasingly becoming an important component that is impacting different business functions. Despite the larger number of users, most SM platforms are primarily generating revenue from advertisements and through affiliate relationships. Businesses can use SM platforms for customer engagement, brand awareness building, marketing, product design and development, sales, and promotion. For each of these areas of business, extant literature was presented along with the examples. Future research in this domain should look at at least four areas design, strategy, management, and measurement from the perspective of users, platforms, and firms. A focus on the developing world as the context will enrich the field by showcasing the differential adoption strategies adopted by or available to businesses. The development of risk mitigation frameworks will be helpful to businesses in dealing with the negative sentiments and other risks associated with the emotional outburst of users. The representativeness of SM data is still an open question and further work to strengthen the methodological rigor will benefit the field greatly.

ACKNOWLEDGMENT

The authors are thankful to Ms. Nalini Srinivasan for wonderful copyediting.

KEY TERMS AND DEFINITIONS

Advertising Model: A revenue model for SM platforms in which brand pages and ad videos

containing product/service information are created on the platform.

Brand Awareness: It is a measure of how identifiable the brand is for target customers.

Brand Community: It is a structured composite of social relationships among the admirers of a brand.

Brand Reputation: It is defined as a measure of how customers react to brand (what they think about the brand, how they talk about it and how their inclination towards the brand).

Customer Engagement: Defines the behaviours evoked in a customer by a specific brand that are over and above a basic connect.

Online Product Review: It is an account on SM of a customer's personal experience vis-a-vis a product.

Revenue Sharing: It means that the revenue made from user generated content, SM platform share some part of it to content creator.

Social Media Marketing: It is a term which describes the actual activities involved in using SM platforms for marketing purposes.

Social Media: Online platforms in which users can create and share the content.

Social Promotion: It can be defined as direct marketing, advertising, and interactive marketing using SM platforms to encourage the sale of products/services.

Subscription Model: In this revenue model, the subscription fees charged for accessing content or services available on SM platform constitute the revenue source.

Samford University, USA

INTRODUCTION

Credit scoring is a method of modeling potential risk of credit applicants. It involves using different statistical techniques and past historical data to create a credit score that financial institutions use to assess credit applicants in terms of risk. Credit scoring is essentially a type of classification problem: which credit applicants should be considered good risks and which applicants should be considered bad risks.

A scorecard model is built from a number of characteristic inputs. Each characteristic is comprised of a number of attributes. In the example scorecard shown in Figure 1, age is a characteristic and “25–33” is an attribute. Each attribute is associated with a number of scorecard points. These scorecard points are statistically assigned to differentiate risk, based on the predictive power of the variables, correlation between the variables, and business considerations.

For example, in Figure 1, the credit application of a 32 year old person, who owns his own home and makes \$30,000, would be accepted for credit by this institution. The total score of an applicant is the sum of the scores for each attribute present in the scorecard. Lower scores imply a higher risk of default, and higher scores imply lower risk.

Credit, as it has evolved since the 1950’s, it is cold and impersonal, completely based on numbers--what you owe, what you’ve paid, how much money you have. The numbers all get hacked down to one number: a credit score. The bigger

and more complex the global financial system gets, the less it cares about anything other than the applicant’s credit score. Banking institutions are becoming less and less personal with online and mobile banking applications. Very few people know the local bank manager at their hometown bank anymore. A credit applicant’s personal story is not taken into account when applying for a financial loan. The credit applicant’s “character” fits into the bank’s algorithms about as well as peanut butter fits into the workings of a Swiss watch.

One consequence of this system is that it is biased against poor people, people with no bank accounts or very little credit history (“thin files”) and young people. These types of applicants cannot obtain credit because they cannot generate the financial metrics that would provide evidence to determine if these applicants should be granted or rejected for a financial loan. It is these several billion people who would be the most enthusiastic first customers of a new kind of credit based less on numbers and more on character. The need to market to and provide credit to these types of applicants marks the emergence of a social media credit score.

This chapter will describe how banks and financial organizations are starting to incorporate big data sources, such as data from social media websites, into the credit lending process. A discussion of how more established organizations, such as FICO and SAS, are incorporating big data in their scorecard methodology will be given. A description of two start-up companies

Figure 1. Example scorecard

Example Scorecard

Let Cutoff=500

A new customer applies for credit.

AGE 32 120 points

HOUSE OWN 225 points

INCOME \$45K 200 points

Total 545 points

ACCEPT FOR CREDIT

Characteristic Name	Attribute	Scorecard Points
AGE	Up to 25	100
AGE	26-33	120
AGE	34-45	185
AGE	45+	225
HOUSE	OWN	225
HOUSE	RENT	110
INCOME	Up to \$10K	120
INCOME	10K-25K	140
INCOME	26K-35K	160
INCOME	36K-50K	200
INCOME	50K+	240

which are using electronic and big data sources such as social media to provide banking services and grant loans will be discussed.

BACKGROUND

The statistical methods used to categorize objects into groups can be traced to 1936 in Fisher's publication (Fisher, 1936). Durand (1941) was the first to use Fisher's methodology to distinguish between good and bad loans. Using this research, the founders of credit scoring, Bill Fair and Earl Isaac, built the first credit scoring system for the United States in 1958. Although credit scoring has been in use since that time, it is only recently that credit scoring has become widespread.

There are some older, yet still very relevant, credit scoring resources that discuss the statistical issues in developing a credit scorecard (Siddiqi, 2006; Thomas, Oliver, & Hand, 2005; Hand & Henley, 1997). These references provide a traditional framework that credit analysts have used in the past to develop credit scores.

As with any other business sector that is highly data dependent, the credit scoring world

has felt the impact of the big data phenomenon that is sweeping through modern businesses (Lohr, 2015). Banks are moving away from using traditional statistical techniques to build a credit scorecard. Financial organizations are combining the traditional techniques with new big data technology and big data analytics to build their scorecards. With the rise of companies using social media data as a tool to build better predictive models, financial institutions are integrating big data sources in calculating credit risk (Fei et al., 2015). Recently, even Facebook is hinting at entering the social media credit arena. Facebook has recently made its Messenger application the ability to make financial payments, similar to Apple Pay. What is interesting about Facebook's decision is that it will allow Facebook to collect data on their customer's financial payments and coupled with the already-abundant social media data it has, this decision allows Facebook to become a stand-alone financial lending institution that can incorporate character into the credit score (Maney, 2016).

Wei et al. (2015) provide the most contemporary and comprehensive review of incorporating social media data into an applicant's credit score.

The article examines credit scoring models that are built with and without social media data in order to study whether the incorporation of social media data into a credit score provides an advantage to financial lending companies. The article also examines whether potential credit applicants change their social media profiles and perhaps start making more strategic social media connections once a credit applicant knows they are being assessed based on their social media activity and persona. And, lastly the paper examines how incorporating social media provides a more even-level playing field for some of those disenfranchised groups that have been traditionally overlooked.

MAIN FOCUS OF THE ARTICLE

In the last several years, financial institutions have begun exploring ways to incorporate an applicant's social media activity such as Facebook and Twitter into the risk associated with a loan. The main advantage for a financial institution using such expanded data sources is the shorter time frame to deploy a credit scoring model. In a traditional credit scoring scenario, it can take 12 to 18 months to update a scorecard model with new data. This time lag results from lenders having to verify the new data, determining if the new data impacts other departments of the institution, and taking time for employees to learn how to use the new information to make decisions on credit worthiness, pricing and cross-selling (Adams, 2012).

Another advantage of using big data sources such as social media data is that social media data allows financial institutions with a broader view of the applicant's background other than traditional data sources, such as the bank's own customer data. The type of data collected from social media sources is wide and varied and provides insight into an applicant's lifestyle and behaviors. Social media data can provide genuine demonstrations of behavior that point to an applicant's capability and likelihood of meeting repayment terms. For those applicants

with "thin files" or young people, utilizing social media data to establish a credit footprint may be a sensible idea (Thomas, 2015).

By using big data sources and the associated big data analytics, a bank can increase:

- **Efficiency:** Is essential to banks that collect and analyze vast volumes of data. Accessing and analyzing various types of structured and unstructured data as soon as it is captured is essential in staying relevant to electronic banking customers.
- **Profitability:** Big data sources allow a bank to reach customers in ways that were never possible. By using online banking and social media applications, a bank can correspond with a customer at precisely the right time through online campaigns and messaging.
- **Customer Interactions:** Many banks are using big data and social media sources to shift their focus from product-centric to customer-centric. The bank's goal is to understand what the customer needs from each banking interaction so that each point of contact with the bank will be ideal. Big data analytics mine millions and billions of rows of customer and transaction data in order to develop specialized campaigns and offers for the customer.

A specific facet of big data is information collected from social media. Using social media data is still an evolving avenue for many financial organizations. Social media is one of the most effective ways to find out what customers like and do not like, as well as the type of banking relationship the customer expects from the financial institution. Social media can be used as a marketing tool for a bank; in a recent article, Ally Bank utilized social media exclusively to promote retirement products (DePaula, 2015). The aim of the social media campaign was to encourage younger people to start thinking about and saving for retirement but also to engage a retiree crowd over the age

of 65. Some of the social media campaigns Ally developed was to give away \$150 gift cards to generate interest in savings accounts on Pinterest, created Google hangouts and Twitter chats so that people could talk about retirement and savings, and created YouTube videos. The benefit of creating a social media marketing campaign for Ally is that the interest does not immediately dwindle like a traditional television or radio ad. Bank customers have the ability to keep the conversation going.

Another aspect of social media that banks are leveraging is customer activity on social media sites; this would be used to calculate part of their credit score. Banks hope to use social media activity to develop a sort of social media credit score. This concept is based on the traditional credit score, but it is very difficult to define exactly how to calculate a social media credit score. Currently, a social media credit score concerns how others in your social network view you. For example, what would be the impressions of a bank official if he were to research you? Are you an influential person -- that is, do you have the power to persuade others in your social network to buy a product you recommend, or sign up for a particular service? Are you positive or negative regarding the social media decisions you make? Financial institutions are currently turning the answers into these questions to develop a financial measurement and use that measurement either as a component of traditional credit scores or as the sole credit worthiness measurement of a customer.

What exactly constitutes social media activity? Below is a list of common social media outlets that banks access to develop a social media credit score.

- **Facebook:** The world's largest social media site is a wealth of information for anyone permitted access using the 'friend' status. Anyone who is a friend can see your profile and information unless the appropriate privacy settings are activated.
- **Twitter:** 140 characters can say a lot about someone, as this messaging system proves. Many Twitter fans tweet about themselves

daily. Searching Twitter can reveal any comment a person has made about themselves or someone else.

- **LinkedIn:** LinkedIn is an online resume network. You can post current and past jobs, active organizations, and awards.

One way that financial institutions are measuring a customer's social media influence is using a Klout score. Klout is a social credit score (Wagstaff, 2012). Klout measures an individual's influence online, with influence defined as the ability to drive others to action. When online content is produced, Klout looks at how the individual's network responds to that content. Klout takes in data from social networks and gives an overall score based on online influence. The data is from public networks such as Facebook, Twitter, Google+, LinkedIn, and Foursquare. Klout process about 3 billion pieces of content and connections daily and produces a new, accurate score for each Klout member every morning (Fernandez, 2011).

In the sections that follow, we will examine how organizations are incorporating big data sources such as social media into their banking and credit scoring applications.

FICO

FICO is a leading analytics software company, helping businesses in 90+ countries make better decisions that drive higher levels of growth, profitability and customer satisfaction. The company's groundbreaking use of big data and statistical algorithms to predict consumer behavior has transformed entire industries. FICO provides analytics software and tools used across multiple industries to manage risk, fight fraud, build more profitable customer relationships, optimize operations and meet strict government regulations. Probably the most well-known analytical tool is the FICO score, the standard measure of consumer credit risk in the United States.

FICO has recently started experimenting with incorporating social media data into their

credit scores. FICO has determined, using big data algorithms to analyze social media, that if a potential credit applicant has used the word ‘wasted’ in their profile that it has predictive power of whether the applicant is going to repay a loan or not (Hardekop, 2015). However, just because FICO has figured out this ‘nugget of gold’ in the big data landscape, it does not mean that FICO is using social media data to construct a credit score. In fact, FICO does not use social media data to calculate a credit score due to regulatory restrictions. However, FICO is piloting a new score called FICO Score XD that does incorporate big data sources. This credit score is aimed at the cohort of individuals that the Introduction section discusses; people who have no credit history or are invisible to the credit scoring system. FICO Score XD incorporates mobile phone, utility, and rent payment histories, property and tax data are also incorporated into the credit score. According to Christina Goeth, a FICO spokeswoman,

FICO Score XD is currently designed to only score consumers that are not scorable with traditional credit data. The algorithm checks to determine if a traditional FICO Score can be generated first, and if it can, the traditional score is returned to the lender. If it cannot, FICO Score XD provides a second chance to get approved. The goal of FICO Score XD is to expand access to credit. (Selyukh, 2016)

SAS

SAS is well known for its analytical software. SAS offers a series of products aimed at credit risk managers, such as SAS Credit Scoring for Banking and SAS Real Time Decision Manager. Credit Scoring for Banking mines and organizes data, then uses that information to develop consumer scorecards and perform compliance with Basel II requirements for management of credit risks for pools of loans. Decision Manager produces real-time recommendations via data channels such as websites, call centers, and ATMs to aid

a bank in making credit management decisions such as loan approvals and credit card increases. To further speed updates and expansion of data used in scoring, SAS’s High Performance Analytics searches data sets that include billions of information items to locate correlations between different data sources that can be combined to accelerate the development of new predictive scorecards.

Lenddo

One of the larger players in the social media credit scoring business is Lenddo. Lenddo is one of the more established companies, with its inception in 2011. The co-founders of Lenddo realized that more than one billion people in developing countries were starting to move into the middle class and would need access to credit (King, 2014). The initial intent of Lenddo was to offer small, targeted loans to individuals in developing countries. The purpose of the loans was to give the rising middle class in developing countries access to credit, as many individuals in these countries lack credit histories because there is no financial infrastructure for an applicant to establish a traditional credit history. The purpose of Lenddo loans must be to enrich the customer’s life through education, healthcare, or home improvement. These loans could work well for an individual who wants to take a career-development class, but lacks cash and cannot qualify for a traditional loan due to a lack of credit history. The applicant can leverage what he or she does have -- a connected network of online friends and colleagues.

Lenddo uses non-traditional data sources to compute applicant’s credit scores. Lenddo uses only social media data to determine the creditworthiness of applicants (Anderson & Hardin, 2014). To apply for a loan, the first step in Lenddo is to create a profile and upload a photo to the website. Then, the individual connects to social networks and invites friends and family to be part of what Lenddo calls the “trusted network.” Lenddo uses a social network algorithm to evaluate the “trusted

network” and develop a Lenddo score. The higher the Lenddo score, the more access to loans an applicant will have. If the applicant is granted the loan, the applicant’s entire social network is kept informed of the applicant’s payment history (Anderson & Hardin, 2014).

Moven

Moven, formerly known as Movenbank is currently generating excitement with their use of social media data in a banking environment. Moven is a completely online and mobile company; its motto is “no paper, no plastic, no hidden fees” (King, 2012). The bank has no physical locations and will not issue any physical debit or credit cards. The premise behind Moven is that it will control the digital front end of the customer relationship and partner with traditional banks to handle the deposits. Moven provides financial services through a mix of mobile and web modes such as banking applications enabled using smart phones.

The founding of a company like Moven is in response to banking customers living in a digital age. A recent study showed that it is not only millennials that are wanting personalized, anytime, anywhere services from their banking relationships. Cisco conducted a survey of over 7,000 individuals in 12 different countries and found that there was a gap between the consumer behavior and their current bank’s ability to offer personalized and convenient services and products (Cisco, 2014). To understand and respond to digital customer’s better, Moven is providing applications that offer real-time banking advice and incorporate social media data into the development of a credit score.

Moven recently developed a smartwatch application that gives a customer real-time banking information and budget advice. The new timepiece version of the app provides a stripped-down analysis of the wearer’s spending habits. For example, as a customer walks out of Starbucks, the application provides an alert telling how much was just spent and whether the customer is in good shape budget-wise or should start using the office Keurig. The

application’s spending meter turns red, green or yellow depending on how much the customer has spent overall in the current month versus the previous month (Crosman, 2015).

Moven is using social media profiles including Facebook, LinkedIn, and Twitter to determine personality traits about a consumer which might help to predict their ability and willingness to payback credit. Movenbank uses the personal information stored in social media sites such as Facebook to construct a one-on-one personal financial relationship with the customer. Online engagement methods such as messaging will also encourage customers to increase money in their savings accounts.

Moven has developed a product called CRED™ score, which combines traditional scoring elements and social media data. Moven seeks to determine a sort of digital credibility standing of a customer using their social media information. Taking into account an individual’s traditional credit score in addition to a customer’s use of digital payment channels, social connectivity and money management beliefs, CRED™ score assesses risk as well as a customer’s financial potential. Unlike a credit score, CRED™ score is designed to be a sort of financial health or wellness score, like a calorie counter on your phone – a score that goes up when a customer gets better at saving or managing their money (Moven, 2016). CRED™ score is trade-off for individuals who use it, where individuals have to be willing to share their social data to participate in building better financial health.

FUTURE DIRECTIONS

As we become more and more of a digital society through online banking and shopping, there are several areas of technology that will see drastic changes in the financial field.

- **Storage:** Hard drives, jump drives, and servers will soon be items of the past. New

emerging technology will be needed to collect, store, preserve, manage, and analyze unstructured streaming data that social media outlets produce.

- **Commerce:** In time, all credit agencies and financial organizations may use social media information as a component of a consumer's credit score. As more shopping moves online and physical money such as \$10 and \$20 bills are vastly becoming digital 1's and 0's, it will more important to calculate the financial risk of individuals.
- **Software Developments:** In the next few years, we will see the development of distributed computing technology, such as Hadoop, to perform serious scalable computing. New advances in big data analytics will be developed to deal with the flood of web data produced from clickstreams from a website with millions of users.

More credit data is available than ever before through unstructured data sources and social media outlets. The challenge for banks and other financial institutions is to quickly capture that data and make decisions. Similarly, the credit industry has never experienced such a growth of available data. The challenge will be to invent innovative credit scorecard models that can rapidly adapt to changing data in real-time.

CONCLUSION

Modern data processing systems have ensured that virtually all banks and financial institutions have rich data sources to mine. However, merely having volumes of data is no longer a source of competitive advantage. Data has become a commodity and therefore needs to be honed and enriched further to derive that extra advantage needed to differentiate results. Therefore, to form and sustain a differentiator strategy, the existing data has to be supplemented with unstructured

and social media data sources to give the overall information a whole new dimension.

The rapidly expanding social media arena provides a new source of information flow. Tapping into the collective intelligence and sentiments of the crowd through aggregated mining of their social posts provides clues to consumer thought. At a bank, the concept of the 360-degree view of the customers ascends to an entirely new level in the context of accessing their social media interactions.

KEY TERMS AND DEFINITIONS

Credit Score: A measure of risk associated with how likely an individual is to re-pay a financial loan.

Hadoop: Open source software that stores and analyzes massive unstructured data sets.

Klout Score: A Klout score is a numerical measure on the scale of 1 to 100 that measures how influential an individual is in an online social network setting. The higher the Klout score the more influential the individual is considered. For example, is a person influential in getting others to buy a product or sign up for a service.

Social Media: A web-based social outlet. Social media may be in the form of online web-sites that allow individuals to communicate and

establish social networks such as Facebook and web-based videos like those viewed on YouTube.

Social Media Credit Score: A measure of social risk that is created using information from social media outlets.

Structured Data Source: Data that contains an identifiable structure. Structured data is typically stored in traditional databases with identifiable rows and columns.

Tweet: A posting on the social media site Twitter that consists of 140 characters or less.

Unstructured Data Source: Data that has no defined identification such as e-mails, images, text and web logs, and videos. Unstructured data is data that is not contained in a database.

S

Social Network Analysis and the Study of University Industry Relations

Fernando Cabrita Romero
University of Minho, Portugal

INTRODUCTION

The methodological approach of Social Network Analysis (from now on, abbreviated SNA) can bring many benefits for the study of university and industry relations (from now on, abbreviated UIR). Relations between university and industry are important in innovation studies because they can be considered as an innovation network, in the sense that the interactions established by their participants have more or less defined innovation goals (Mansfield & Lee, 1996). SNA is the study of social structure (Wellman & Berkowitz, 1988). It describes a group of quantitative methods for analysing the ties among social entities and their implications (Wasserman & Faust, 2007). With the use of SNA it is possible to explore and to better understand different innovation outcomes involving UIR, by analysing the different measures and the structure of the social network. In this work the SNA methodological approach is described and its fundamental concepts are presented. The paper then reviews the applications of this approach on the study of the relationships between university and industry. The paper aims at systematizing the available information and knowledge, highlighting the main research pathways, the main conclusions and pointing possible future research questions.

BACKGROUND

UIR is an increasingly important and researched phenomena. Theoretically and structurally, the theme is linked to the study of the innovation process and to the need of understanding it and in-

fluencing it. Linear perspectives of the innovation process placed the university at the beginning of a linear sequence of innovation and the firm at the end of it, largely ignoring the interaction between the two types of institutions. New, interactive, dynamic, complex perspectives see the innovation process as a system involving many institutional actors, as a network of relations and as a complicated web of knowledge exchange and utilization. Science and technology are increasingly complex and costly and no single actor commands the necessary resources, relying on multiple sources of information and knowledge exchanges that are crucial for a successful innovation process. In this context, and considering the many types of relations and actors that may be possible in the innovation process, the relationships between academia and industry stand out as particularly relevant, because of the type of institutions that participate and the nature of the information and knowledge that is exchanged. The literature on UIR has raised many issues on the theme, and debates are ongoing, which can be found in some review articles (Baldwin & Green, 1984; D'Este & Patel, 2007; Perkmann et al., 2013). Only some of the issues and debates will be explored here, namely those researched by SNA concepts. They will be referred in more detail in the following section, along with the presentation of the results of the literature review, which is the main focus of this work.

SNA is the study of social structure using a group of quantitative methods. It analyses ties among social entities and looks for key players and group patterns. SNA uses concepts that are related to the structural properties of the network

and indicators that are related to relational properties of the network. The most used concepts related to structural properties of the network in UIR studies are the concepts of density, component, and subgroups. The most used social network analysis concepts related to relational properties of the network are the concepts of degree centrality, betweenness centrality and geodesic distance.

The concepts related to structural properties of the network are basic and important concepts that characterize the overall structure of the network. Through the concept of density (which indicates the level of connection between all the nodes of the network) it characterizes its global cohesion. Through the concept of component (which indicates the existence of large groups inside the network) and through the concepts of subgroups or cliques (which indicates the existence of smaller, cohesive, specifically defined groups) it characterizes its internal structure. The combination of these indicators and an adequate interpretation of their meaning provides useful descriptions and characterizations of the network, in terms of the position of their nodes and constituents. The characterization is frequently complemented with visual aids, namely through sociograms. Sociograms are diagrams composed of nodes and lines. The nodes are the actors of the network and the lines are the connections between the actors. The concepts related to relational properties of the network are often at the centre of the analytic procedure, and are used in several ways according to specific research objectives. The concept of degree centrality (which indicates the extent of a node connection) identifies the most connected actors. The concept of betweenness centrality (which captures the intermediary nature of a particular node's connection) is used to identify and characterize the intermediary positions of actors in the network. Besides the main concepts referred above, other concepts related to these ones are also used, but less often. All these concepts are mathematically defined, but it is beyond the scope of this paper to provide detailed algebraic specifications, which are available in several books (Scott, 2000; Wasserman & Faust, 2007).

THE LITERATURE REVIEW

General Aspects and a Synthesis of the Main Results

There is not a great number of articles that addresses specifically the problem of UIR using SNA techniques. There is a variety of perspectives that reflect specific and idiosyncratic concerns of the authors. Few papers follow the same guidelines or share identical perspectives. However, there are small groups of authors that build on past works or use identical databases, such as patent databases.

In terms of the main study object or main research preoccupation the studies can be classified in the following categories: 1) the study of the characteristics of personnel/institutional networks that are prominent in university-industry relations; these studies generally rely on the use of patents that are co-produced jointly by university and non-university members, and the patterns of collaboration are analysed; 2) the study of university-industry relations in the context of specific industrial settings or in the context of specific institutional conditions; these studies may rely also on patent databases but other types of data may be used, either primary data, obtained through questionnaires, or secondary data, obtained through diverse documental sources; 3) the contribution of the study of university-industry relations to the validation of theories; these studies also rely on a mix of patent, primary and secondary data.

In addition to these themes there are other themes that are addressed in these studies, either in a parallel way or as themes that frame the former or the research approach. The themes that could be common to the papers are, in broad terms, the three main themes above indicated but, within each one, the approach and main research concerns and targets are quite different. The literature will be analysed not through the lens of the broad themes, but through the details of the specific papers. This methodology will permit to extract from the papers the main academic debates and to highlight the respective contributions to

knowledge. The next sections will perform that task. Table 1 synthesises the results.

The table indicates the main identified concepts on UIR that have been researched using SNA. It is possible to divide those concepts in four groups. The first one includes the two first concepts, which are related to intrinsic structural properties of the network. The second group includes the two following concepts, which are related to institutional and knowledge characteristics of the network. The third group includes the next three concepts, which are related to specific patterns found in networks. The fourth group includes the last two concepts of the table, which are related to the validation of existing theories. The last concept

is related to the search for new methodological approaches, mainly related to the use of new data sets. The main results and the literature for each concept will be described and explored in the following sections.

Strong and Weak Ties, and Structural Holes

The influence of the nature of the relation on the performance of the network is a debated issue. The concepts of strong and weak ties were introduced by Granovetter (1973). Strong ties represents strong and regular interactions between the actors

Table 1. University-industry relations and social network analysis: main debates and conceptual propositions arising from the literature review

Main Concepts	References (Authors, Year)	Conceptual Propositions Proposed by the Literature
Strong and weak ties, structural holes	(Gilsing & Duysters, 2008; Rost, 2011; van der Valk, Chappin, & Gijssbers, 2011; Villanueva-Felez, Molas-Gallart, & Escriba-Esteve, 2013)	• Balanced social structures (strong ties with some weak ties) seem to be more innovative. • Differential outcomes on the nature of knowledge contingent on the specific balance of the structure of social capital.
“Small worlds” networks	(Balconi, Breschi, & Lissoni, 2004; Guan & Zhao, 2013; Protogerou, Caloghirou, & Siokas, 2013; van der Valk et al., 2011)	Networks with high clustering and short average geodesic paths are more conducive to inventive or innovative activity.
Open-science and proprietary technology	(Balconi et al., 2004; Jason Owen-Smith & Powell, 2004)	• The institutional attributes of open science and proprietary technology influences network structure. • Open science networks are more connected and dense than proprietary networks that are more fragmented and disperse.
Knowledge base and environment as relational factors	(Gilsing & Duysters, 2008; Krätke & Brandt, 2008; Leydesdorff, 2004; J. Owen-Smith, Riccaboni, Pammolli, & Powell, 2002; Plum & Hassink, 2011)	Different knowledge bases affect network structural properties, the position of individual entities in the network and their capacity to access knowledge
Patterns of university-industry relations	(Gilsing & Duysters, 2008; Krätke & Brandt, 2008; Leydesdorff, 2004)	• Patterns are influenced by regional industrial structures. • Biotechnology has a specific pattern of university-industry interaction.
Public research organizations as central actors in innovation networks	(Breschi & Catalini, 2010; De Stefano & Zaccarin, 2013; Lissoni, 2010; Minguillo & Thelwall, 2012; Protogerou et al., 2013)	• Academic authors-inventors assume more brokerage positions. • Public research organization are at the centre of innovation programmes.
Influence of commercial orientation on fundamental science production	(Balconi & Laboranti, 2006)	Academics more connected to industry are more productive in scientific terms.
Industrial districts	(Capo-Vicedo, Molina-Morales, & Capo, 2013; Morrison, 2008)	• Public research organization as main intermediaries of knowledge flows to the district. • Weak knowledge exchanges but strong information exchanges inside the district actors.
Triple-helix theory	(Heimeriks, Hörlesberger, & Van Den Besselaar, 2003; Khan & Park, 2013)	• Triple helix assumptions on institutional role intersections are supported. • Multiple communication channels with differential roles in the Triple Helix relation.
Methodological contributions	(Heimeriks et al., 2003; Kim, 2012; Minguillo & Thelwall, 2012)	Asides from patents indicators, other indicators and data unmask fundamental structural or relational properties.

(nodes) of the network and weak ties represent sporadic and temporary interactions.

Coleman (1988) claimed that cohesive groups and strong ties were effective ways to coordinate an exchange of knowledge flows, while Burt (1992) argued that strong ties resulted in redundant information and that innovation required new knowledge inflows and perspectives coming from weak ties. Unfulfilled connections between groups with internal strong ties are said to be structural holes, which can be filled by specific actors, with strong intermediary positions. Villanueva-Felez et al. (2013) apply these concepts to assess in which way the structure of researchers' social capital affects academic performance. The authors distinguish between academics that are completely embedded in a network that has no weak ties (establishing links with members of his or her own department, without ties with government, industrial, or other societal actors), academics which are in a network that is formed predominantly by weak ties, and academics that are in an integrated network that contains both strong and weak ties. The results show that the academics in the network with no weak ties are the less productive. On a study of a network of inventors and on the assessment of the impact of patents (based on forward citations) and integration of knowledge (based on backward citations), Rost (2011) concludes that inventors with balanced social capital (strong ties but also some weak ties) come up with the most innovative solutions, or integrate the most knowledge or have the highest impact on future knowledge. He concludes that Coleman's and Burt's perspectives are complementary and that in the presence of strong ties, weak network structures (structural holes or peripheral position) leverage the strength of strong ties in the creation of innovation. Similar arguments are advanced in a visual network analysis of two government sponsored programmes that aimed to foster innovation through public-private partnerships (van der Valk et al., 2011) and also by other studies of university-industry relations or industry networks (Ahuja, 2000; Gilsing & Duysters, 2008).

"Small Worlds" Networks

The open science characteristics of scientific communities translate, in social network terms, into the so-called networks with "small worlds" characteristics (Albert & Barabási, 2002). The small world properties, in the context of scientific networks in a specific discipline, are defined by the existence of a large component connecting almost all nodes and within the large component, all nodes (scientists) are close to each other (Albert & Barabási, 2002; Newman, 2001). These characteristics of academic networks are not found in networks of non-academic inventors, except in since-based fields. The influence of small world properties on innovativeness is addressed in studies of industry networks (Verspagen & Duysters, 2004) and in university-industry networks (Guan & Zhao, 2013), and generally considered to be positive, although there are disagreements concerning this positive influence (Fleming, King Iii, & Juda, 2007).

Open Science and Proprietary Technology

The analyses of patent databases provides the basis for the exploration of another important concept, which is debated in multiple forms and in its multiple consequences in studies of university-industry relations, which is the distinction between the characteristics of open science and proprietary technology (Cowan & Jonard, 2003; Merton, 1957). The debate can be inserted in a larger debate concerning the influence of diverse institutional conditions on processes of relations between organizational entities. Balconi et al. (2004) conduct a study of Italian academic and industrial inventors whereby, departing from assumptions on the behaviour or characteristics of "open science" networks and "proprietary networks", expect to find differences between the networks of academic and non-academic inventor. In fact, the study found that networks of industrial inventors are much more fragmented

than networks of academic inventors, except in the chemistry field (defined in a broad sense, i.e. including biotechnology). The chemistry sector, science-based field, was different because it was influenced by the institutional weight of scientific inputs in commercial technology.

Knowledge Based and Environmental Conditions as Relational Factors

Other articles support the importance of environmental factors in shaping specific properties of networks. A study of the Boston biotechnology sector (Jason Owen-Smith & Powell, 2004) found that the information flows between the actors of the network, which included firms and public research organizations, depended not only on network participation and geographic proximity, but also on the institutional characteristics of the network. In public-dominated networks firm performance depended only on net participation, unlike in networks dominated by private entities, where innovative performance depended on position factors, i.e., their closeness to central actors (although this characteristic was weak in terms of statistical significance).

An important determinant of cooperation between university and industry, and an important factor in terms of innovative performance, seems to be related to the position of the firm in the network. That position may be related to geography (Balconi & Laboranti, 2006) or that position may be related to the knowledge base that the firm possesses and that may confer the firm the possibility to connect with more or less central actors of the network. A study of an industrial network in Germany (Cantner & Graf, 2006) argues that a prerequisite for future cooperation is not based on past cooperation but rather on a shared knowledge base. It puts in question ideas that argue that persistent cooperation, based on trust, is necessarily the basis for collaboration. In

a study of two industrial networks (biotechnology and multimedia) in a period that was characterised by the transition of an existing dominant design and a shift away from rules, norms, routines or activities, Gilsing and Duysters (2008) argue that environmental conditions related to different knowledge bases, and the validation and selection mechanisms inherent to each of the two fields, explain the relational and structural properties of the two networks. For instance, the connection of public research organizations is centrally present in the biotechnology field but absent in the multimedia field (Gilsing & Duysters, 2008).

Differences in the knowledge base show up as an important factor in the determination of collaboration structures in another study involving biotechnology firms in a regional context (Plum & Hassink, 2011). It points to differences related to internal competencies of the firms regarding differential capabilities in terms of the nature of the knowledge required to develop the differential products of each firm, in which the knowledge of the market also has a role.

Although in a quite different perspective, a study of the differences between the structures of two networks emphasises the importance of environment in shaping the properties of the network (Capellari & De Stefano, 2014). Patents that are owned by the university (which is the assignee) or invented by the university (the university is not the assignee but at least one of the inventors is a tenured academic), are analysed separately, showing differences in terms of size of components, number and size of subgroups and the brokerage position of inventors. The institutional factors are mediated by two universities that have different policies related to patenting ownership.

Patterns of University-Industry Relations

Databases on scientific literature have been extensively used to analyse the patterns of collaboration

between scientists. Patent databases are also being explored to analyse the patterns of collaboration between academia and industry.

An exploratory analysis of the simultaneous embeddedness of researchers in scientific and technological networks (Breschi & Catalini, 2010), which compares networks of authors, inventors and authors-inventors, and the overlap between them, argues that author-inventors play a crucial role in connecting the two other networks (only authors and only inventors) and occupy important positions in each community. The role of academics as fundamental intermediaries between public and private research is explored in a study (Lissoni, 2010) that finds that academic inventors tend to be more central actors in broker and gatekeeping positions, although strong brokerage positions are very few and held by scientist with many patents and publications. De Stefano and Zaccarin (2013) reach similar conclusions regarding the larger relational activity of academic authors-inventors vis-a-vis industrial authors-inventors.

Two important differences were also apparent in Balconi et al. (2004): academic inventors were more connected than non-academic inventors, and had a more central position. The central position of academics, or of the university, is a characteristic that often shows up in analysis of networks where public research organisations are involved (Balconi & Laboranti, 2006; Breschi & Catalini, 2010; Jason Owen-Smith & Powell, 2004; Protogerou et al., 2013).

The knowledge base of patents is researched to see how much innovation is really based on science (Leydesdorff, 2004). This question is important because theories about university-industry relations are historically influenced by the biotechnology sector. The biotechnology is a science-based sector whose inventive activities tend to be performed in close collaboration with public research organizations and whose output is patented through co-authorships or co-assignments between academic and industrial inventors. The access and the analysis of patents

databases have become easier and many studies have thus relied on these data to infer general conclusions to other fields of science, that are not so formalized in terms of literature relations. The study analysis two sets of patents, extracted from the USPTO, one based on patents that have a university as a co-assignee, and another that has a Dutch address as an assignee. The structure of the co-words networks linking patents and their citations to other patents and scientific literature is analysed. The analysis is entirely based on the visualization of sociograms, while nodes are (co) words). The two networks are quite different. In the set of university patents (which represents university-industry relations) the fields of biotechnology and molecular biology dominate the set and the knowledge base of the patents, and the visualising shows a neat organization around the intellectual organization of the disciplines. In the set of Dutch patents (representing the knowledge base of the international economy) the visualization shows a recognizable representation of the Dutch industrial structure with a dominance of electro-technical and chemical applications and large multinational corporations. Although biomedical application integrates the patents they are not central to the whole set. These results strongly suggest that inferences of university-industry relations based on literature and patent analyses are heavily conditioned by the specificity of the biotechnology sector.

Public Research Organizations as Central Actors in Innovation Networks

The central position of public research organizations shows up in descriptive analyses of networks that involve heterogeneous actors. Both a study of the network structure of science parks (Minguillo & Thelwall, 2012), using web links as indicators of connections, and a study of the collaborative networks established during the seven Framework Programme on Research and Technological De-

velopment of European Commission, show the central position of public research organizations. In the study of science parks, governmental agencies also play an important role, and in the case of the Framework Programmes, although firms are present in larger numbers, they are not the central actors.

Influence of Commercial Orientation on Fundamental Science

The impact on fundamental research of an orientation to patenting and commercialization has been researched through the relationship between patenting activity and publication record of university researchers, and in general the results point to a positive correlation between patenting and publication activity (Czarnitzki, Glänzel, & Hussinger, 2009). This theme is revived with a social network approach (Balconi & Laboranti, 2006) and the results support the positive relationship between publication record and patenting activity. The author argues, in line with other similar arguments (Rosenberg & Nelson, 1994), that industry feeds on academic research but that academic research also needs inputs from high technology industries in order to find direction to its research. So, academics that are close and collaborate with industry producing patents are also the ones that are more productive in purely scientific terms.

Industrial Districts

There is a strand of research of university-industry relations using social network analysis methods that adopt a deductive approach and try to validate some relatively entrenched conceptual implications of some theories.

One of the researched theories looks at the implications of the industrial district approach. Morrison (2008), in her study of the furniture sector in Italy, argues that the community of informal ties appears to be rather small and that

'know how' sharing is also rather limited, contrary to assumptions from industrial district theorists that based their ideas on the development of these concentrated regions on intense knowledge exchange between the actors. It, however, supports the argument that public research organizations, more than large firms, play a central role and as intermediaries in the knowledge flows for innovation that occur in the industrial district, and that knowledge for innovation does not arise only from the close interactions of the firms of the district, an idea that is also supported by a study of a Spanish textile industrial district (Capo-Vicedo et al., 2013).

Triple-Helix Theory

The implications of the triple-helix approach are also examined. Using webometric indicators and semantic analysis of the contents of the webpages Kim (2012) found that university and industry websites were similar, thus suggesting there is an intersection or interchangeability of the roles and function of the two types of organizations, as suggested by the triple-helix theory (Etzkowitz & Leydesdorff, 1998). Diverse channels of communication and relations between the diverse institutional actors (co-authorship, participation in projects, information diffusion) is also explored in Heimeriks et al. (2003) which argues that each communication channel or media has different functional purposes in maintaining in the maintenance of the links of the triple-helix relation.

Methodological Contributions

Finally, there is a search for alternative methodological approaches and indicators in the studies of networks of university-industry relations. Some authors propose the use of webometric approaches (Kim, 2012; Minguillo & Thelwall, 2012) and other authors propose the use of simultaneous indicators of relational characteristics, such as citations, project participation, questionnaires or

other data (Almodovar & Teixeira, 2014; Furu-kawa, Shirakawa, & Okuwada, 2011; Heimeriks et al., 2003), arguing that analysis based on a single indicator underestimate the level and may not capture all of the complexities of the col-laboration patterns.

FUTURE RESEARCH DIRECTIONS

Some possible research paths are open. Eventually, the use of more complex and elaborated concepts of network analysis could improve the analysis of data, it may have the potential to reach different or stronger evidence and conclusions, and it may be an aspect that must be improved. The diversity and plurality of university-industry relations has not been properly addressed in the literature, which tends to use patents as indicators of collaboration. New sources of data must be explored. Environmental and institutional influences of diverse sorts are clearly very important factors that condition and determine university-industry relations, and research is open to greater exploratory efforts. There is a considerable potential to test theoretical and conceptual propositions which are assumed but have scarce empirical support.

CONCLUSION

The use of social network analysis in the study of university-industry relations was reviewed in this study. There are not many studies that combine the two perspectives and the ones that exist fol-low different research objectives and concerns and different methodological proposals. It seems evident that this particular knowledge quest is in a highly exploratory phase. Nevertheless, the contributions to knowledge have been varied and important, ranging from purely descriptive stud-ies and methodological explorations to deductive testing of established theories.

KEY TERMS AND DEFINITIONS

Betweenness Centrality: A social network analysis measure that indicates how much a node is in the middle of the connections between other nodes.

Degree Centrality: A social network analysis measure that indicates the number of other nodes to which the node is connected.

Density: A social network analysis measure that describes the level of linkages between nodes in a network. The more nodes are connected to each other, the denser the network is.

Innovation Process: Is a complex social and technical process that transforms ideas and

technologies into new or improved products or services.

Open Science: Open science is generally, but not exclusively, performed in university settings and is characterized by the wide non-commercial dissemination of research results and scientific knowledge.

Proprietary Technology: Is characterized by the appropriation by private entities of specific claims on technology, generally, but not exclusively, through the legal mechanism of patenting.

Social Network Analysis: A methodological approach that employs quantitative techniques to analyse social structures.

Strong and Weak Ties: A strong tie represents a person with whom there is a regular interaction, and a weak tie represents a person with whom there are sporadic or punctual contacts.

Structural Holes: The connection potential between elements or groups of elements that are not connected.

University-Industry Relations: A set of connections between people in university and people in industry. There are many forms of relations, including informal ones (the flow of graduates to industry, mobility of researchers, public meetings, professional networks) and formal ones (research contracts, licensing, joint labs).

Social Networking and Knowledge Sharing in Organizations

S

Sarabjot Kaur*Indian Institute of Technology Kanpur, India***Subhas Chandra Misra***Indian Institute of Technology Kanpur, India*

INTRODUCTION

Employees working in an organization have both explicit and tacit knowledge. Explicit knowledge is easier to document and share than tacit knowledge which stems from practical and experiential understanding. Solutions to contemporary business problems can be achieved by utilizing the available expertise spanning across different functional areas of an organization (Wenger & Snyder, 2000). Staying connected helps in advancing the understanding about various functional domains and helps in generating a multi-perspective outlook for tackling any issue. One such way of staying connected can be achieved by using social networking tools within the organizational boundaries. Yammer, Salesforce Chatter, Microsoft Sharepoint online are a few examples of collaborative and social tools used in enterprises. Enterprise wide social networking can help in connecting people from different backgrounds and domains making it easier to transfer knowledge to wider audiences (Riemer & Scifleet, 2012). The present chapter draws from extant literature to highlight the usefulness of social networking for knowledge sharing purposes along with discussing the relevant factors and adoption issues.

BACKGROUND

In its simplest form, social networking can be described as the use of internet technology to

create and share user generated content by a web of people connected with each other online. Sophia van Zyl (2009) defines social networking as “applications or websites that support the maintenance of personal relationships, the discovery of potential relationships and should aid in the conversion of potential ties into weak and strong ties, by utilizing emergent Web 2.0 technologies.” Social networking allows people to make connections, join groups of their interest, contribute information and discuss issues of relevance. All this is accomplished through various modes such as online communities, blogs, discussion forums and other online collaborative tools.

Enterprise Social Media

An emerging trend in the use of online collaborative tools in organizational context is Enterprise Social Media (ESM). Leonardi et al. (2013) define enterprise social media (ESM) as “web-based platforms that allow workers to communicate messages with specific coworkers or broadcast messages to everyone in the organization; explicitly indicate or implicitly reveal particular coworkers as communication partners; post, edit, sort text and files linked to themselves or others; view the messages, connections, text, and files communicated, posted, edited and sorted by anyone else in the organization at any time of their choosing.” ESM is an effective platform for connecting people across functional domains and making visible the information shared with a wider

audience. Similar to popular social platforms like Facebook and LinkedIn, ESM platforms may vary in the functionality offered and features supported but primarily they serve similar inherent purpose of bringing people together facilitating information flow and knowledge conversations, crowd source solutions across multiple domains, share relevant expertise and foster collaboration (Riemer & Scifleet, 2012).

SOCIAL NETWORKING AND KNOWLEDGE SHARING

Nature of Knowledge

Every organization wants its employees to share their knowledge with their co-workers as it will eventually benefit the organization in terms of improved performance. Knowledge exists in explicit and tacit forms. While explicit knowledge is easier to communicate and acquire, tacit knowledge is acquired by way of practice and encompasses skills and experiences held by people. It is difficult to document and explicate tacit knowledge as it is embedded in action and involves commitment (Nonaka, 1994). Such knowledge is helpful when there is a specific problem to be solved. The knowledge seeker approaches the potential knowledge provider with the problem and a solution can be reached by consensus after considering the circumstantial issues and making appropriate judgments. Creative solutions can be achieved by mutual knowledge sharing leading to enhanced creative performance when employees search information, share and co-create more information by way of interactions and discussions thereby adding to existing knowledge base of discussants (Sigala & Chalkati, 2015).

Interactions Over Social Media Platforms

Social media platforms can be instrumental in facilitating the above said interactions where it

can occur in the form of immediate unplanned instances or in events of specific information needs (Subramaniam & Nandhakumar, 2013). Tracking the activity of individual users can give a fair idea about their interest areas and relevant domain expertise (Kane, 2015). It leads to an overall understanding about the tacit knowledge resources possessed by various employees, a phenomenon termed as “ambient awareness” (Leonardi & Meyer, 2015).

Social networking tools enable collective completion of task with virtually co-present actors (Subramaniam & Nandhakumar, 2013). Problems can be viewed from different perspectives and social networking tools can be instrumental in crowdsourcing solutions by integrating cross functional expertise (Mäntymäki & Riemer, 2014). Thus, collective intelligence enabled by inputs from various sources across organization has significant potential of improving work performance leading to survival and growth in contemporary competitive environment. Although technology is adopted with intentions of functional improvement and advancement of organizational performance, its actual usage is imperative to understand its effects on organizational variables. Some of the factors that have an influence over knowledge sharing are listed below.

Social Ties

Social networking tools may help in fostering and maintaining connections that can be used to facilitate such discussions subsequently leading to consensual viewpoint on the issue. Strong social ties enhance the knowledge sharing behavior among employees (Chow & Chan, 2008). Dyadic knowledge exchange is enhanced in case of the virtual communities supported by social networking as it increases the possibility of frequent communication and increased flow of information among the dyads (Pan et al., 2015). Hence, better mechanism can be in place to increase the social interaction in both online and offline modes (Chen & Hung, 2010) along with shared goals (Chow &

Chan, 2008) to foster better understanding among the group.

Shared Goals

Shared goals have an indirect effect on knowledge sharing intention among coworkers. Also, a sense of being a part of the group instills a responsibility towards knowledge contribution in the group (Chang & Chuang, 2011). An environment of equality among individuals can also help in facilitating knowledge sharing (Yu et al., 2010). Working towards a collective goal can help to generate knowledge contributions from all members of a particular community.

Social Trust

Social trust influences knowledge sharing intentions (Chow & Chan, 2008; Din & Haron, 2012). Intensive interactions and mutual trust leads to more reliable knowledge sharing (Chang & Chuang, 2011). Strong interpersonal trust helps in reposing faith among knowledge seeker and provider thereby easing the transfer. However, fostering trust online is not always possible and the same can be accomplished by way of bringing people together in offline situations too (Chen & Hung, 2010).

Reciprocity

People want to share their knowledge as they feel that they need to reciprocate the help they received earlier (Yu et al, 2010; Chen & Hung, 2010). Thus, a knowledge contribution initiated by one member can lead to a chain of reciprocal responses adding to the cumulative knowledge base of its members.

Self-Efficacy

Individual self-efficacy will lead to higher contribution towards knowledge sharing activities (Hsu

et al., 2007). Relative advantage of the knowledge sharing exercise, the belief in one's own abilities (Hsu et. al., 2007) and mutual understanding among the knowledge partners helps in facilitating the sharing process (Chen & Hung, 2010).

Relational Context

Mechanisms to support and foster knowledge sharing vary according to relational context (Boer et al., 2011). The congruency between the relational assumptions of knowledge contributors has an effect on the sharing behavior. Similarity in assumptions about knowledge and the respective knowledge communities facilitates knowledge transfer.

Sharing Culture

The overall culture of the organization plays an important role in knowledge sharing activity. Highly open members view such platforms as the opportunity to discuss ideas, have opinions and debate issues along with coming up with potential solutions to problems with the help of mutual knowledge contributions (Yu et al, 2010). Social networking can be even more effective in an environment conducive for utilizing it to its best potential. Cultural norms affect the employee mindset and subsequently their need to seek collective expertise (Patroni et al., 2015). Employees may explore an area in greater depth due to both competitive and collaborative intent which eventually expedites their learning (Patroni et al., 2015).

Motivation

People are motivated by extrinsic and intrinsic rewards in respect of sharing their expertise or domain knowledge. Sharing knowledge over social platforms leads to an increase in the reputation of the knowledge provider which serves as an incentive and further increases both the quality and the quantity of the content shared (Hung et al., 2011).

Apart from this, intrinsic factors like altruism also affect the knowledge sharing behavior positively (Ma & Chan, 2014).

Similarity

Lingual similarity can enable better exchange and understanding which leads to subsequent effective exchange of information (Chang & Chuang, 2011). Similarity of status and location of an individual in the hierarchy may also have an effect on the knowledge sharing behavior. As the individual experience increases, members tend to share more with the people of similar expertise than with similar status (Hwang et al., 2015).

Context

Social networking acting as a medium of knowledge exchange eventually effects employee performance. However, the effect on performance differs according to task context (Kuegler et al., 2015). Performance varies in inter-team and intra-team conditions. Inter-team task context requires the contribution of novel ideas and new information suitable for innovative performance in contrast to intra-team usage where routine task specific information is required (Kuegler et al., 2015).

Excess Information

Too much information on social networking platform can even create clutter and make things worse as it may become difficult to find the relevant information. Different conversation threads may be difficult to follow. There can be attention conflict which may undermine the purpose of generating an overall awareness about knowledge conversations in the organization (Leonardi, 2015).

ADOPTION ISSUES

Any new technology should be viewed from multiple perspectives before introducing it in

the organization. Thus, actors at organizational, individual and technological level are considered for successful adoption and post-adoption usage of social networking tools. Organizational support in terms of user awareness and training is required for increasing the self-efficacy of users. Moreover, motivational support in terms of recognition and reputation feedback (Hung et al., 2011) can lead to more positive contribution by users. Purpose of social networking tools in organization, participants, and adequate risk analysis along with policy mechanisms should be considered before taking any decision to adopt such a system (Turban et al., 2011). Individual acceptability can be increased by ensuring the ease of their functional operation. Individual tendencies like self construal and interdependence (Liu & Rau, 2014) should be considered in adoption decisions. Also, individual usage is increased to as much as 25% when peers are using a given social media technology (McKinsey, 2015). Relative ease of use will render the tools accessible thereby increasing the possibilities of their continued usage. Existing usage of social networking tools in popular context can be examined to design tools that allow for added functionality as per organizational requirements. 35% of companies from a data set of 1500 were reported to adopt ESM platforms following the adoption by competitors (McKinsey, 2015). Irrespective of the reasons of adoption, it is the prerogative of company to decide about the extent of identity to be revealed. More identity leads to accountability while anonymity may help to raise genuine concerns and provide way for unique solutions (Kane, 2015).

FUTURE RESEARCH DIRECTIONS

Although social networking is a widely researched area, there are many aspects that can be taken up for future research in the context of its usage in organizations. Social networking is having an impact on the way people connect and share with each other. However, there can be instances

of misunderstandings due to poorly represented information which can be explored in respect of collaborative work. In addition, there is a need to explore these tools in light of design constraints. Often these tools are third party applications and may not be fully in sync with organizational or group requirements. Having a user oriented perspective in this regard can advance the design research in finding better ways to adapt them to organizational peculiarities which may be quite distinct from general and popular designs. Working in groups fosters collaborative thinking but excessive interaction over social networks may be a source of proliferating groupthink among employee which needs to be researched further. People tend to avoid any controversial and political issues in organizational communication. Hence, sharing in case of sensitive or political information is also another potential area worth exploration which may lead to interesting results.

CONCLUSION

Contemporary organizations are primarily knowledge driven. Knowledge is a co-created phenomenon. Organizations are employing various tools to provide employees with the right knowledge at the right time. Social networking tools have been used in variety of ways to make this knowledge exchange easier and accessible to employees. The article was an attempt to highlight some factors that have an influence over the knowledge sharing behavior of employees in an organization. However, there is still a need to consider various structural and design issues so as to fully harness the functionality of networking platforms. Along with structural improvements, successful implementation and usage of these platforms requires a conducive culture with organizational support. These are just means that can be utilized to the best of their potential by employing them in the right conditions.

KEY TERMS AND DEFINITIONS

Altruism: Intention or action showing selfless concern for others potentially benefitting the receiver.

Self-Efficacy: The belief in one's ability to accomplish a task successfully. It affects the way an individual approaches the task.

Social Ties: The connections with fellow individuals in one's communication network. Information moves in different ways across various social ties in a social network.

Tacit Knowledge: The knowledge which is acquired by experience and practice, often difficult to explicate.

Virtual Communities: A group of individuals communicating over a social network to accomplish a shared goal.

Web 2.0: Web characterized by interactive and collaborative user generated content. The information generated is more dynamic in nature.

Understanding the Potentials of Social Media in Collaborative Learning

INTRODUCTION

Social media is a potential technology to support collaborative learning practices. This chapter illustrates the potential benefits of using social media in collaborative learning. To explain the potentials of social media, the first part of the chapter discusses the nature of the social media technologies and web 2.0. The second part illustrates the idea and importance of collaborative learning to address the changing demands of the 21st century. After introducing the fundamental concepts and ideas related to social media in first two parts, final section discusses the potentials of social media in collaborative learning following with a discussion section and a summary in the conclusion section.

BACKGROUND

Web 2.0 and related developments enabled the growth of social media concept. Web 2.0 provides both technical and philosophical bases that empower the underlying properties of social media. Web 2.0 created a new opportunity for the end users to feel related to the other users and/or institutions who are the creator, co-creator or shareholder of the content. The latest development in the Web 2.0 technology offered a platform that allows internet users to create and share many audio-visual knowledge artifacts (Yengin, 2014 a). Especially, the user owned content creation

and sharing qualities makes Web 2.0 empowered social media services as a potential platform for collaborative learning, in which the working together and co-creation of knowledge is essential.

The idea of using social media for learning is widely discussed in the literature (see following sections). Since there is a literature already discussing the social media in learning in general, this chapter aims for turning our attention to a more specific discussion on the potentials social media brings for collaborative learning activities. Hence, to analyze the issue with a comprehensive understanding, this chapter discuss the underlying mechanisms of Web 2.0 that empower the social media concept, definitions of social media with examples and list of social media services, dynamics and importance of collaborative learning in modern education and connections between collaborative learning and social media.

SOCIAL MEDIA

Before starting to talk about social media, it should be defined with a clear distinction from the interchangeably used terms such as “social networking”. Social networking is defined in Meriem-Webster dictionary as “forms of electronic communication (as websites for social networking and microblogging) through which users creates online communities to share information, ideas, personal messages, and other content (as videos)”. The same dictionary defines the social media as “a

creation and maintenance of personal and business relationships especially online”.

Several authors defined “social networking” as a venue for users to share their activities and interests with others in a particular community (Fenton, 2012). Social networking allows users to have an online profile in a bounded system to connect with other users to communicate and collaborate (Boyd & Ellison, 2007).

Different authors defined “social media” as a way of creative expression (Gauntlett, & Thomsen, 2013; Zagalo & Branco, 2015), exchanging user-generated content (Kaplan & Haenlein, 2010), spreading and sharing meaningful and valuable content (Jenkins, Ford, & Green, 2013) in a culture of collaboration and connectivity (Dijk, 2013) using web technologies such as web 2.0 (Power 2007 ;Tuten 2008 & Brown 2009).

Although dictionaries and different authors make an attempt to define the “social networking” and “social media” to show that these are not exactly same terms, people often use the term of “social networking” and “social media” interchangeably (Cohn, n.d.). This confusion could be a result of the lack of clear cut between social media and social networking concepts. To approach this issue of providing a clear and definite deception of “social networking” and “social media”, this part will provide literature about the common and different properties of these terms and provide a short and practical definition.

The basic commonalities of “social networking” and “social media” are that they both rely on the internet as a communication channel. Another common property between two is allowing people to interact in social ways. The online social interaction or online sociality is defined as “collective action, communication, building communities, connecting and networking, creative content making, collaborative knowledge building, sharing, playing etc.” by Fuchs (2013).

Comparing social media and social networking terms, the main difference is that social media allows publication of knowledge. The two main distinctive characteristics of social media are en-

abling the participation and power of publishing (Hanna, Rohm & Crittenden, 2011). While social media is related to user-generated publishing and distribution of the content knowledge, social networking creates the necessary basis and a technical framework for the social media to live on.

Interestingly, a social networking service may change its characteristics within time and transform to a social media platform. For example, a study (Kwak et al., 2010) showed that hat users’ way of using social networking tool may re-define it as a social media platform. In their study, researchers crawled 41.7 million user profiles, 1.47 billion social relations, 4, 262 trending topics, and 106 million tweets to analyze the topological characteristics of Twitter, which is an online social networking service allowing users to follow and being followed on published content (Kwak et al., 2010). According to the results of this study, Twitter had become a social media platform even though it had started as a social networking service.

As seen with the examples, sometimes the precise categorization of the technologies and services as social media or social networking platforms may be impractical since the terms are used changeable by many people and the services may transform to a different nature in time. For practical reasons of avoiding confusions, the definitions would be that the “social media” as the services that allow users to generate and share content online and the “social networking” as the services that allow to managing the relationships in online social communities.

In addition to the definitions, seeing the examples of social media services may be more helpful for readers to better understand the social media services. Using website traffic data from different sources, eBizMBA Rank website (2016) published the following list in Table 1, showing the most popular 15 social media and social networking services as of Feb 2016.

These social media services can be categorized in two formats: “users’ profiles based” and “content-based services” (Kamila & Bhattacharjee, 2014). User profile based services focus on

Table 1. The most popular social media and social networking services as of Feb 2016

Service	Estimated Unique Monthly Visitors
Facebook	1,100,000,000
Twitter	310,000,000
LinkedIn	255,000,000
Pinterest	250,000,000
Google Plus+	120,000,000
Tumblr	110,000,000
Instagram	100,000,000
VK	80,000,000
Flickr	65,000,000
Vine	42,000,000
Meetup	40,000,000
Tagged	38,000,000
Ask.fm	37,000,000
MeetMe	15,500,000
ClassMates	15,000,000

content and connections around the profile of a member of the service (e.g. personal info, hobbies, likes-dislikes, interest etc.) and the content-based services emphasis on the content development and publishing, while still providing pages of public profiles and connections.

For example, the first 3 in Table 1 are the users' profiles based social networking services emphasizing connecting with users (both in professional and non-professional manner) who are usually like-minded in order to share content and ideas for creating new knowledge using the power of the crowds in a networked community. Pinterest and Instagram may be categorized as the content-based networking services in which the produced user' contents are stored in an archive or a repository like services and stored in a social network (Andersen, 2007).

SOCIAL MEDIA AND WEB 2.0

Currently, social media technologies depend on Web 2.0 technology. In order to understand the social media, it is important to take a look at the

term of Web 2.0 technologies and its distinctive properties. Web 2.0 allows making connections through individuals, creating collaborative communities, publishing of user-generated content, integration of multiple source of knowledge and communication, using mash-up strategies to integrate many contents and harnessing collective intelligence in a decentralized manner using web services and cloud computing (o'Reilly 2007 ; Rouse & Haughn, n.d.).

Before Web 2.0, Web 1.0 offered a limited way of connection between individual users. In order to create a community, the website author, who is the only sole owner of the content, had to create a circle of connections (Fuchs et.al. 2010). Also, the publishing in Web 1.0 required a set of skills in website building and programming. Web 2.0 removed such barriers for the end users and empowered them to connect each other and become the owner of the content (Gylfason, 2010). For instance, users can co-create Web 2.0 content as a story by performing distributed comments and discussions in addition to editing and manipulating the text and pictures in the story (Alexander & Levine, 2008). In such a scenario, a reader or

a follower of the story can contribute to the story development and become a co-author. Participating in the content creation in collective interactions rather than just the consuming the information, users build collective intelligence in communities (O'reilly, T., 2007).

Shortly, the changing role and interactions between web users in production and distribution of information brings new possibilities in the intellectual growth of the societies. These possibilities provided by Web 2.0 and employed in social media platforms open new ways for activities in collaborative learning.

COLLABORATIVE LEARNING

The first idea of collaborative learning term was developed in the 1950s and 60s by a group of secondary school teachers (Bruffee, 1984). It is a type of learning experience in which learners work and be in a learning process together (Whipple, 1987). In the research literature, collaborative learning is described as cooperative activities in the educational context (e.g. reviewing course book together or sharing assignments etc.), as joint problem solving in learning processes and/or as a development of a lifelong learning process evolving in many years in communities such as in professional work field (Dillenbourg, 1999). Collaborative learning improves the relationships intensity between learners, create dynamic communicational flow, reduce duplication, lower the risks and increase reward satisfaction once the students achieve their learning goal (Keas & Mandell, 2009).

Supporting collaborative learning is important to prepare learners for the future business world. Today's economy demands the creation of new ideas and products in collaborative ways (Bonnet, 2016). The latest changing global environment forces us to move on knowledge economies (Quinn, 1992; Acs, de Groot, & Nijkamp 2013; Jorgenson & Vu, 2016), which are economic models that growth is dependent on the knowledge to generate values.

Knowledge economies need the establishment of decentralized business structures and frameworks (Madanipour, 2013) to allow the creation of economic value by employing knowledge in goods and services (Crevoisier, 2016).

This new way of doing business requires us to adopt the idea that "the creation and broadcasting of the knowledge is shifting from centralized points – where the knowledge is accumulated in entities that are controlled by certain stakeholders (e.g. teachers, books, agencies) to more distributed points – where the knowledge is created and distributed by the well-connected users in the networks" (Yengin, 2014). In order to successfully respond the changing dynamics of the new economy, institutions controlling the policies of the education systems should create new learning strategies that allow addressing the requirements and demands of this new economy. To adopt the requirements of the new economic systems in which social media plays an important role (Choi, Huang, Palmer, & Horowitz 2014), education may need to make a shift from the factory model of learning environments toward a collaborative learning environment in a social networked setting (Quintana et al., 2016; Baumeister 2005; Gibson 2006).

POTENTIALS OF SOCIAL MEDIA IN COLLABORATIVE LEARNING

Recent studies already discussed the rise (Zawacki-Richter et al., 2015) and importance (Ford, Bowden, & Beard 2011; Popescu 2014) of social media in facilitating the collaborative learning activities. Rather than focusing again on the increased used and the importance, this part focuses on functional potentials of social media collaborative learning to give the reader wider perspectives on the possibilities with social media in collaborative learning.

Before starting presenting the potentials of social media, it should be kept in mind that the social media is not an ultimate solution to all col-

laborative learning activities. First of all, social media cannot be considered as the exact replacement of face to face communication which has many benefits and superiorities over the digital communication channels (Hiltz & Turoff, 1993; Daly, 1993). Rather, social media should be considered as a supplement or an expanded way of computer-mediated communication (Watson & Hill, 2015) that allows remote communication, documentation and recording of communication, creating channels to allow generation of more ideas and have greater equality of participation (Bordia, 1997). Similarly, social media is not an exact replacement of face to face social and collaborative learning activities in the classroom, especially for friendship building for social well-being. Several authors discussed that there is no relationship between friendship quality based on social media use and well-being of students (Wang et al., 2014); but negative social well-being was positively associated with levels of uses of media (Pea et al. 2012). These authors and studies add weight to the argument that teachers and students should not use the social media as an entire replacement of traditional collaborative learning activities in the classroom, but use the social media as a supplementary communication method.

Although social media is not an exact replacement of face to face teaching, it brings new opportunities and changes for education in institution level and pedagogic level. In institution level, it is a fact that using social media for collaborative learning activities require several transformations in policies. Social media is highly influencing the educational institutions to change their traditional way of doing business in order to keep their competitive power and to strengthen their services providing cost effective and personalized learning activities, compared to the traditional learning environments (Dabbagh & Reo, 2010). To implement collaborative learning activities with social media, schools should change their processes to address issues such as “meeting specific the learning objectives, time constraints, complexity of classroom management, constraint on Internet

access, limited social media tools in schools, teachers’ limited understanding of using social media and limited guidance” (Bull et al., 2008).

In the pedagogic level, social media also introduces new approaches to the collaborative learning. Several studies showed that social media services provide new appealing and engaging learning activities since it allows applications for self-motivated, autonomous and personalized activities. In other words, the allowance of self-motivated, autonomous and personalized learning is the why the social media would be a good supplementary method for collaborative learning. For example, authors (Junco, Heiberger & Loken, 2011) investigating the impact of social media use on 125 students’ learning and engagement showed that using social media tool (Twitter) for the different academic activities and co-curricular discussions may highly engage both students and faculty to collaborate actively to the learning process. In addition to engaging activities, authors also reported that social media has effects on students’ positive feelings to collaborative activities (Hung & Yuen 2010) and social media is engaging with self-motivated and autonomous collaborative activities in and out of the classroom (McGloughlin & Lee, 2010). Also, several authors discussed that the basic elements of social media support creation of personal learning settings which lead to self-regulated learning experiences which are essential in collaborative learning (Dabbagh, & Kitsantas, 2012; Dabbagh & Kitsantas, 2013).

In addition to potentials described above, another answer for why social media is beneficial would be that the social media’s role in positive community building for collaborative learning. For example, in social level, social media creates a cycle in which students collaborate on learning task to build knowledge and create new ideas while socializing and communicating. Community engagement creates opportunities for students to participate in events and collective activities. In such social media enabled collaborative learning communities, students may construct a digital identity (Dalton & Crosby, 2013) and develop

social skills (Bauman and Rivers, 2015), form online friendship (Koutamanis et al., 2013), build rapport (Cain et al., 2013) and show responsible communication patterns to satisfy their psychosocial needs (Manago, Taylor, & Greenfield, 2012).

Ultimately, establishing good relationships and friendship are important factors in collaborative learning activities. Thus, using social media for altering the communication for friendship and the roles in a learning community becomes an important effect of social media. For example, social media addresses this by providing communications platforms for understanding and being aware of own and others' emotions, which also influence collaborative learning performances (Chanel et al., 2016).

Having argued why social media engage students' positively in learning, this part focuses on answering of for what kind of activities and when social media should be used. Actually, research showed that students use social media as guided collaborative learning activities include socializing purposes (meet other students), asking questions during self-studies, exchanging documents and making literature reviews and preparing for exams (Zawacki-Richter et al., 2015). In another earlier study, authors reported that students use social media for doing daily multi-tasking, developing friendships in a networked way, building knowledge and learn collaboratively in a decentralized way (Ulbrich, Jahnke & Martensson 2011).

Although social media provides positive potentials and opportunities as discussed above, introducing social media to the class without the teacher facilitations will not bring out these potentials. The role of the teachers' becomes a critical success factor. Students shouldn't let to use social media for learning purposes without any guidance and pedagogical strategy employed by teachers. A study (Selwyn, 2009) conducted to investigate 909 students' education-related use of social media, illustrated that students interactions are not related to academic tasks when there was no guidance and pedagogic strategy. To put it another way, using social media in learning should be guided by the

teachers. Once it is a guided activity, it opens many positive ways to collaborative learning as explained above paragraphs.

As teachers' roles become critical, teachers' pedagogic styles and use of social media should be also discussed to benefit from the social media. For example, similar to the students' usage, a survey conducted with thousands of participants (Stansbury, 2011) showed that teachers use social media mainly for networking with colleagues, using real world examples in learning, collaborative learning activities, communication, creating assessments, accessing the parents, announcements, community outreach and professional development. Another study (Moran, Seaman & Tinti-Kane, 2011) investigating the faculties attitudes toward the using social media reported that although faculty sees the social media with some value in teaching activates, they complain about the time required to engage in social media activities, and they have concerns about privacy and integrity issues.

To conclude the investigation on the potential of social media in collaborative learning and to comprehend the full potentials, finally, the risk and challenges should be presented. First of all, it should be noted that not every student are readily capable of operating on social media platforms safely. According to recent studies, such students can be exposed to some risk of peer pressure (Milner, 2015), cyberbullying, clique-forming sex abuses (O'Keeffe & Clarke-Pearson, 2011) and privacy issues (Barnes, 2006) while they use social media services. Similarly, a recent report indicated that the privacy of faculty and students is the one of the biggest concern and blockages in adopting social media in the classroom, especially widely used commercial social media tools (Seaman, & Tinti-Kane, 2013).

Several authors also discussed the difficulties that teachers face when identifying the authenticity of the students' thoughts and ideas when they use social media. For example, plagiarism is one of the concerns (Hayes & Introna, 2005; Evering & Moorman, 2012). Keen (2007) argues that using

basic cutting and pasting makes young generation believe that the idea and thought belong to them, which also allows the creation of “younger generation of intellectual kleptomaniacs”. On the other hand, the digital culture brings a new way of learning in which borrowing, sharing or promoting others’ content may be welcomed in some learning fields, if there is an awareness of the risks (Iliescu 2008;). Moreover, guidelines to use social media in learning highly encourages sharing of knowledge with resource citing (Rennie & Morrison, 2013).

Finally, the digital culture difference between students and the adults also may be an issue for using social media in collaborative learning. Teachers and parents who are not savvy in social media culture may not be able to understand the students’ lives which are heavily embedded in the social media culture (Boyd, 2009). Parents and teachers’ lack of knowledge and unfamiliarity of social media use may create a huge disconnection between generations in order to construct social communities to tackle the life and society in general (Yardi, & Bruckman, 2011).

DISCUSSIONS

To adopt social media practices and make transitions, institutions should understand and conceptualize social media as a platform for the community (Hanna, Rohm & Crittenden, 2011). In the education sector, this platform should support the students’ access as well as integration with the current systems. Furthermore, educational institutions should provide infrastructure to implement social media technologies and synthesize them into the existing school learning management system. For instance, social media and other online services of educational institutions should support students’ mobile devices and various operating systems (Zawacki-Richter et al., 2015). Also, web 2.0 based social media services that enable collaborative learning should be embedded into the web-based learning systems.

In order to avoid privacy and reputation issues, educators may be role models of responsible social media usage. They need to avoid conflicts of interest, harming public image of their institutions and creating false impressions that their personal comments are official. Educational institutions need to address the challenges of privacy, plagiarism and other ethical issues by creating policies. There may be also a need for presenting teacher training programs to instruct on the meaningful use of social media technologies in collaborative learning. Also, these institutions should provide guidance for students in using social media and self-regulated learning activities both in formal and informal learning environments.

FUTURE RESEARCH DIRECTIONS

Social media provides different ways of engaging students in collaborative activities. The research on the effects of the risks and benefits of social media in collaborative learning should be extended in order to be able to safely employ the concept with its full potentials while avoiding the risks. In this chapter, a general review of the social media benefits and risks has been provided. However, with a carefully designed study and/or series of studies, it would be possible to have a more specific analysis of social media effects on learning. For example, considering the range of the social media applications with many attributes that may cause multiple effects on different elements of the learning, it may be hard to identify the exact effects of each attribute of social media without controlling isolated effects in experimental studies. As a future research, several controlled studies investigating the effects of social media by isolating the number of variables should be carried. Once such controlled studies are conducted, it would be also easier to compare the social media’s specific effects with other technologies’ effects.

In addition, future research on social media may be extended with the studies that investigate social media effects on the development of skills

that are important for matching the 21-century learning requirements such as collaboration, communication, creativity, critical thinking, problem-solving etc. The future research on the effects of social media also should not be limited only to the positive effects; it should also cover the negative effects such as the likely effects of social media on possibly downgraded writing, face to face communication and attention-focusing skills.

Although there is a need for further research on pedagogic aspects, the social media phenomenon can't be ignored as the previous research literature signals the potentials. Thus, the role of social media in addressing the global changes in the 21 century shouldn't be ignored and there should be more investigations to understand the different forms of social media as well as potential risks and benefits for education to be able to adapt these changes by conducting future research studies.

CONCLUSION

In this chapter, the potential benefits of using social media in collaborative learning have been documented and discussed with examples from the recent research studies. The first part of the chapter investigated the essentials of the social media technologies by reviewing the terminology of social media and social networking with examples of recent social media services, connections to the Web 2.0 and the concept and importance of collaborative learning. The second part of the chapter provided a review of benefits, risks and challenges of using social media which illustrated the potentials of these technologies in a collaborative learning. Finally, the discussion part provided a set of suggestions on using social media in collaborative learning.

In conclusion, social media provides a potential platform for collaborative learning. Social media tools open a way of addressing the changing demands of 21 century. Benefiting from the enabling functions of social media that are

running on the frameworks of web 2.0, students can actively engage in the lesson content building, they become self-regulated learners owning the content rights and the responsibility of their learning as well as becoming socially connected to a learning community while forming a relationship with their learning partners. Teachers, establishing new pedagogic methods to integrate the social media tools into the classroom and curriculum may also be a part and the facilitator of such learning communities. While providing positive potential, teachers and students should be also aware of the risks and challenges of the social media such as peer pressure, cyberbullying, clique-forming, sex abuses, privacy, plagiarism and other security issues.

Finally, adaptation of social media in daily school practices may bring some extra challenges and adaptation obstacles such as meeting specific the learning objectives, time constraints, complexity of classroom management, constraint on Internet access, limited social media tools in schools, teachers' limited understanding of using social media, limited guidance and finding standard measurement and assessment of collaborative learning with social media tools.

KEY TERMS AND DEFINITIONS

21st Century Learning: Cognitive skills required to address the demands and challenges of the 21st century (e.g. creativity and Innovation -inventive thinking, cross-cultural understanding -global awareness and cross-cultural skills, critical thinking, effective communication, collaborating, the flexible & self-directed learning, skills related to being information and communication technology literate).

Collaborative Learning: The type of learning experiences or learning strategies that allow learners to create knowledge and meaning in a form of social construct.

Knowledge Economy: Economic models that based on the growth dependent on the knowledge to generate values.

Social Media: The services that allow users to generate and share content online.

Social Networking: The services that allow to managing the relationships in online social communities.

Web 1.0: This is the first stage of the internet that only allows the static content publication with no option for direct modification and/or creation of content by other users.

Web 2.0: The platform technology that allows making connections through users and user communities to enable users to publish and share user generated.

Using Social Media to Increase the Recruitment of Clinical Research Participants

S

Saliha Akhtar

Seton Hall University, USA

INTRODUCTION

Clinical trials are research designed to evaluate ways to prevent, detect, or treat diseases and conditions (National Institutes of Health, 2015). Despite their importance, it has become increasingly challenging to enroll participants in clinical trials. According to Mahon, Roberts, Furlong, Uhlenbrauck, and Bull (2015), a high number of clinical trials fail to recruit the necessary number of participants. Multiple studies have been conducted to estimate how many fail, and although they vary in the exact number, researchers recognize and agree that insufficient recruitment is a significant problem that continues to exist in clinical trials. As the number of clinical trials increases (Inventiv Health, 2013), as there is an increased focus on research that involves more complex diseases and specialized medicines, and as researchers work to develop treatments that are better targeted to patients (Akhtar, Israel, & D'Abundo, 2015), the problem of insufficient recruitment will continue to grow unless changes are made to the recruitment process.

In general, researchers rely on traditional recruitment methods to enroll participants. Traditional recruitment methods revolve around the physicians and their support staff having the primary role to locate and recruit these participants. This could include them personally recruiting patients, searching their patient databases, or through printed materials such as flyers and newspapers (Tanner, Kim, Friedman, Foster, & Bergeron, 2015). Although these ways can lead to

the recruitment of some participants, they prove to be limited to a small patient population and are not aligned with changing times. In recent years, medical information is becoming more available to patients on the internet. Similarly, according to the Pew Research Center (2014), 87% of adults use the internet. In fact, many patients are now using the internet as the first source to retrieve health-related information such as on physicians, diagnoses, and therapies (Omurtag, Jimenez, Ratts, Odem, & Cooper, 2012). Furthermore, individuals are becoming more informed when it comes to health-related issues and are taking a bigger role in their healthcare decisions. In fact, when experiencing symptoms, many individuals are first searching the internet before deciding to see a physician (Shere, Zhao, & Koren, 2014). Despite this, recruitment strategies have not adapted with these changes. “What most in the industry have not yet adjusted to is the fact that patients and caregivers have changed how and where they seek and find information – especially healthcare information” (Inventiv Health, 2013, p. 6). With individuals using online platforms to retrieve information, this creates an opportunity for research site personnel to use it as a way to relay information on clinical trial opportunities.

More specifically, social media is an online platform where discussions and engagement can take place between individuals, online communities, and research staff (Shere et al., 2014). It is a platform that can be used to discuss or disseminate information on clinical trials. Grajales III, Sheps, Ho, Novak-Lauscher, and Eysenbach

(2014) found that social media is being used to increase and maintain communications across the different stakeholders, which could include communications between research site personnel and potential participants. Therefore, using social media could be an avenue for investigative site personnel to use to disseminate information on clinical trials to potential participants.

This chapter will review clinical research studies that have successfully utilized social media strategies in recruitment, along with the conclusions and recommendations that future researchers should consider when deciding whether to implement this type of strategy in their clinical trial recruitment.

BACKGROUND

Clinical trials are designed with the objective to enroll a specific number of participants who are to receive a specified treatment such as a drug, procedure, or behavioral program (Akhtar et al., 2015). However, trials frequently discontinue, even in late stage Phase III trials, due to failure to accrue (Schroen et al., 2010). The failure to recruit the necessary number of participants can have an effect on the overall success of the study (Embi et al., 2005). Insufficient recruitment could lead to delays in the approval of necessary medications and higher costs due to the extended recruitment period. In addition, the inability for a study to enroll the target sample size can lead to an insufficient statistical power (Carlisle, Kimmelman, Ramsay, & MacKinnon, 2015). This can prohibit the ability to answer the study's research questions or lead to conclusions which are not accurate. Further, the inability to enroll the necessary number of participants can have an effect on all stakeholders including the investigative site personnel led by principal investigators who carry out the clinical trials, and the individuals with diseases or conditions.

Social Media

Social media use is expected to continue to increase. As of 2015, the Pew Research Center found that approximately 65% of American adults use social networking sites, an increase from 7% as of 2005 (Perrin, 2015). Social media are “web-based tools that are used for computer-mediated communication” (Grajales III et al., 2014, para. 5). There are different types of social media platforms including blogs, microblogs such as Twitter, social media sites such as Facebook, and thematic networking sites such as forums that center on a particular disease or condition. The applications are diverse in their traditional primary functions – for example, LinkedIn for professional networking, Facebook for social networking, YouTube for media sharing, and blogs and Twitter for content production (Dizon et al., 2012).

The traditional uses of many of these platforms are evolving into more of knowledge-based platforms. These types of social media applications are now platforms to share new information and encourage the exchange of ideas (Dizon et al., 2012). Therefore, they can be used to communicate in a variety of ways including the sharing and discussion of clinical trial recruitment opportunities. In fact, strategies that inform and educate on the diseases and conditions being studied have shown to lead to the improvement in recruitment (Dizon et al., 2012). Therefore, the benefits for providing this type of information are two-fold – educating the population of interest about the disease or condition and increasing their interest in the research opportunity. Patel, Doku, and Tennakoon (2003) described it as a process of providing information to the potential participants and then creating an interest for the study.

Social media applications and tools are widely accessible and are usually of no to low cost (Dizon et al., 2012). In consequence, they can be advantageous to use versus traditional methods, which are limited to a small patient pool and can be costly

at times. Another advantage is the ability to target specific populations. Social media networks such as Facebook can be used to target specific individuals based on their user profiles and have the flexibility to be changed in real-time if necessary (Frandsen, Walters, & Ferguson, 2014). Therefore, there is the opportunity to monitor and adapt to responses in real-time and maximize the ability to recruit potential participants.

Changing Recruitment Practices

In order to keep up with current trends, it is important to change or enhance clinical trial recruitment practices. Traditional recruitment methods, which entail the physician along with their investigative site personnel as the primary roles to locate potential participants can no longer be the primary method as they are limited to a small group of participants. For example, the literature has shown that traditional recruitment methods exclude minorities populations and women, and thus, they are significantly under-represented in clinical trials. However, utilizing social media as an avenue to recruit participants for clinical research also presents an opportunity to increase the enrollment of these populations. According to Jens Michael Krogstad from Pew Research Center (2015), although there are some differences in the preference of social media sites, Latinos, Blacks, and Whites use social media platforms about the same. Further, research has also shown that women are more likely than men to use social networking sites (Perrin, 2015) and studies using social media in recruitment have been able to successfully them (Fenner et al., 2012; Tweet, Gulati, Aase, & Hayes, 2011; Shere et al., 2014). Finally, traditional recruitment methods also exclude other groups such as those who do not have a primary physician and those in rural areas (Tanner et al., 2015), which is not a problem with social media. Therefore, recruitment through social media can resolve some of the issues that are raised with traditional recruitment methods.

There are advantages to using social media to recruit participants to clinical research and trials. However, the number of clinical trials using social media platforms for recruitment is limited. The next section of this chapter will review some studies that have utilized social media to recruit participants.

Integrating Social Media in Recruitment

One study that implemented social media in the recruitment of a clinical trial focused on women who were either early in their pregnancy or trying to conceive. In this study, the researchers used traditional recruitment methods in the first phase of the study and added in social media as a supplementary recruitment source in the second phase of the study (Shere et al., 2014). The traditional recruitment methods consisted of targeting those women who called a telephone counselling program, using notice board postings, and sharing the brochures during clinic appointments. Potential participants were also identified through patient chart review. After 4 years of using these recruitment methods, the recruitment strategy was re-evaluated and it was decided to not only expand advertising to other healthcare establishments, but to also use social media. In the six months when social media recruitment methods were used, the researchers were able to recruit 12 times more women. The researchers used a variety of social media methods including Craigslist, Facebook, Twitter, and pregnancy discussion forums and message boards such as *Baby and the bump* and *Baby on the way* to post ads on the study. Individuals who were interested to participate in the study were asked to contact the study coordinator. After discussion of the study details with a healthcare professional involved in the study, the potential participants were invited to the hospital to go over the informed consent and to continue with the study. The researchers found that despite expanding the use of traditional methods in the

second phase, social media contributed to a large portion of the recruitment. In fact, 78% of the recruitment was achieved through social media methods. The authors concluded that although traditional recruitment methods were used in both phases of the study, the introduction of the social media strategies led to a surge in the recruitment. Online social media platforms have the ability to access individuals who are actively looking for information about a specific topic, which would lead them to research opportunities, whereas traditional recruitment methods are generally passive recruitment strategies. This goes back to the point made earlier in the chapter that individuals are using the internet as a primary platform to seek information. It is also important to note that the researchers strategically not only used social media platforms which have a wide following and ability to target a large number of people, but they also specifically targeted sections of the social media where a large number of women and families are typically found. The researchers also thought that the social media created awareness to the study that may have led to some recruitment from the traditional methods.

Another clinical trial that used social media for recruitment was a health intervention trial involving young adult smokers. The researchers used a Facebook ad campaign to target and recruit young adults to the smoking cessation study (Ramo, Rodriguez, Chavez, Sommer, & Prochaska, 2014). Thirty-six ads, which included a combination of different ads including sponsored stories and picture/text ads, ran over a 7-week period. The campaign was successful and showed that Facebook is an efficient and affordable method to enroll young adults, especially as the researchers were able to target specific study populations via this method. Due to the success in the targeted approach, the researchers advise that it is possible to target a specific population by location, demographics, and keywords in Facebook. In addition, simplicity seemed to be important in relaying the main study message. Given the limited space available, complex images and too

detailed messaging is advised against as it can lead to confusion and the possibility of the main message being missed. Also, newsfeed ads were found to be more successful than the other ad types in regards to the number of people it reached, the number of times it was clicked on, and its' cost. Moreover, the researchers found that Facebook is an effective way to reach a very large sample of young adults across the United States in a short amount of time. However, it is also important to point out that using Facebook may limit the generalizability of the sample population. In this study, the sample population was predominantly non-Hispanic Caucasian urban-residing men compared to what is reported in the literature. Therefore, it is suggested that future researchers use other social media platforms, which although might be used less overall, will have a stronger appeal to specific populations. For example, research has shown that that Twitter has a higher appeal among younger adults, urban dwellers, and non-whites (Duggan & Smith, 2013).

Another smoking cessation clinical trial also attempted to explore the advantages of online social media for recruitment. The researchers explored the feasibility of social media recruitment in a clinical trial evaluating the effectiveness of a behavioral support program on smoking cessation (Frandsen et al., 2014). This study used a combination of both traditional and social media methods for recruitment. The traditional recruitment methods consisted of flyers around two university campuses and ads in newspapers. The social media recruitment method consisted of multiple Facebook advertisements that included different wording and logo combinations. When an individual would click on the advertisement, it would direct them to another website where they would receive brief information on the study and a link to enter in their contact details so they could be contacted to be screened for the study. The researchers closely monitored the advertisements, activating and removing them based on the number of clicks and the capacity at the investigative sites. Similar to the previous

studies, the researchers targeted a specific population – adults living within a certain distance from the sites. The researchers were able to enroll 51.9% of the participants through the Facebook advertisements. Although the participants who were recruited via social media were seven years younger than those who were recruited through the traditional methods, there were no other differences in the characteristics between them. It is also important to note that in this study, the cost of online advertising was found to be more than the traditional method of advertising the study in the newspaper. In fact, the online advertising cost two times more per participant versus the traditional recruitment methods. However, Frandsen et al. (2014) note that this is an estimate and various factors can affect the cost and determining the exact amount. For example, a higher percentage of contacts from the social media avenue ended up enrolling in the study, perhaps because they had more detailed information on the study prior to screening, not only lowering the cost of sharing information but also expediting the process up to enrollment. Based on the results of the study, the researchers recommend using online social media to advertise as a supplement to traditional recruitment strategies.

Another case study that will be presented is a research study conducted by researchers at Mayo Clinic who utilized social media for the recruitment of their study. A member of a social networking site approached the researchers to perform research on her condition, spontaneous coronary artery dissection (Tweet et al., 2011). The researchers who recognized the value of increasing their knowledge of this condition designed a pilot study. The researchers used Inspire, a social networking site for women with heart disease, to recruit women who self-identified with spontaneous coronary artery dissection. The study is different from the others presented as it both recruited and collected data from the participants purely online. The researchers were able to recruit the target sample size of 12 after just one week of receiving IRB approval. Given the already established use of

Inspire for sharing information on heart disease, resources, and opportunities, the researchers were able to utilize this strong aspect of the platform to recruit the participants and collect their medical records and imaging data. The pilot study illustrated the advantage of using a disease-specific social networking community online to recruit for their study. Their study also demonstrated that social networking can enable research participant engagement and lead to recruitment. Furthermore, although recruiting potential participants with rare diseases and conditions can be challenging, the study demonstrated that it might not be difficult when using a social networking platform.

The last study that will be discussed is an online preventative intervention study. The Mood Memos study was a randomized controlled trial with the objective to evaluate if promotional messages could improve self-help behaviors for depression (Morgan, Jorm, & Mackinnon, 2013). Participants were to receive emails over six weeks, which encouraged the use of effective self-help strategies. A variety of online-based sources were used to recruit participants over 14 months, which included Google advertising, Facebook, forums, links from websites, online community noticeboards, and email groups or lists. The researchers tested Facebook but found it to be less cost-effective than advertising on Google so did not continue with it. Also, other researchers have found, Facebook is a useful platform for targeting populations with specific demographics. However, as this study was not targeting specific demographic populations, the researchers did not find Facebook to be a viable resource. Surprisingly, this study also did not find online depression forums to be good recruitment source. The researchers did a search through Google and Bing and followed links from other sites to identify appropriate forums. Permission was received from less than half of the 58 forums that were approached. While smaller forums did give permission to post, it was found that it was a time-consuming process to post and moderate responses. Moreover, recruitment via this method

was found to be limited as many of the individuals did not meet the eligibility criteria. Although the study was able to demonstrate that it is possible to recruit a large sample size purely through online sources, there was difficulty recruiting through them; however, the most effective method was found to be Google.

The next section will discuss some of the key pros and cons from the studies discussed and provide some guidance on what future researchers and investigative site personnel should consider when deciding whether to use social media as a recruitment method.

FUTURE RESEARCH DIRECTIONS

As the studies presented in this chapter have found, there are both pros and cons to using social media in the recruitment of clinical trials. One of most commonly reported benefits of using social media in recruitment is the ability to have a wider reach and to be able to use a targeted approach to find the right participants. Traditional recruitment methods are considered to be mostly a mass advertising approach while social media has the ability to target specific demographics and populations. As clinical research becomes more focused, it will become even more important to find the right patients. Another positive aspect of social media, specifically when focusing on established online community networks and forums, is the ability to share information and research opportunities with individuals who are already well-connected and involved with the sharing of information around a specific disease or condition. These individuals are more likely to be interested to learn and potentially participate in research opportunities.

On the other hand, as Morgan et al. (2013) pointed out, there are also some difficulties in using social media. Unlike traditional recruitment methods, in order to be the most effective, social media recruitment methods require continuous monitoring and effort, especially since they are in “real-time.” Shere et al. (2014) recommended

closely monitoring response rates and revising methods based on responses. In fact, the dynamic nature of social media compels researchers to continuously monitor ads and postings to determine if changes are needed based on the responses received. This will help ensure that the recruitment strategies that are implemented are the most appropriate at any given time. In addition, there have been conflicting findings in the literature about the cost of using social media for recruitment compared to traditional methods. Frandsen et al. (2014) estimated the cost of using social media to be more compared to traditional recruitment. However, they also note that this can vary study by study depending on various factors. Finally, it is also important for researchers to be cautious about the potential security and confidentiality issues that could occur with social media. Just like with most information that is online, there are some concerns that are introduced when social media is used for participant recruitment. Bull et al. (2011) discussed a study that used Facebook in trial on preventative HIV education. They found that confidentiality and data security concerns may be raised when using social media in research.

Future research studies should consider utilizing social media for recruitment in order to have the most efficient process. While no formal guidelines have been set forth by health authority agencies on how future research studies should use social media for recruitment, there have been some recommendations set forth by researchers on how to successfully use this avenue as a recruitment strategy. Shere et al. (2014) first recommended understanding the target population in order to be able to determine which platforms would be the most appropriate for them. In doing so, the researchers are not just using an approach that is geared to the general population, but instead are taking into account the characteristics of the targeted population and utilizing an approach that would be best geared towards them. In turn, this will help ensure that the recruitment strategies are best tailored for the targeted population. Another way to maximize the recruitment process would

be to use a variety of recruitment methods in order to maximize the reach of potential participants and to be the most time- and cost-effective. Shere et al. (2014) recommended using a combination of passive, broad-spectrum and targeted, active recruitment techniques while Inventiv Health (2013) specifically proposed using a combination of social media methods and traditional methods. Both of these ways could help increase the efficiency and probability of successful recruitment. Further, similar to the suggestion by Ramo et al. (2014), Inventiv Health (2013) also noted that information and advertisements on social media should contain terms that are understood by the population and to ensure simplicity through empathy and clarity. Through simplicity, there is a greater probability that the social media user will understand the message that is being conveyed. Moreover, through all of these approaches, future research can maximize on the benefits of social media in recruitment.

CONCLUSION

Traditional recruitment methods are no longer viewed as the most effective way to recruit participants to clinical trials. The ability to access healthcare information on the internet has paved the way for patients to become more involved in their healthcare decision-making. In turn this means that investigative site personnel should consider providing information on diseases and conditions as these patients can then become potential participants. Further, by using social media platforms to share health-related information and clinical research opportunities, there is an ability to reach potential participants who might not have been reached through traditional recruitment methods. Social media allows investigative site personnel to reach a larger patient population and a more diverse patient pool, including those populations who have continuously been under-represented in clinical trials such as minorities and women. Although there is still a need for

investigative site personnel to have a formal set of guidelines to follow when using social media recruitment practices, there are some studies and recommendations that shed light on how to achieve success through this type of recruitment strategy.

Recruitment strategies need to shift to an approach that is not only more targeted, but also has a larger reach. By evaluating the success of studies that have used social recruitment strategies so far, it is evident that future researchers can also achieve recruitment success through social media. Social media could be a promising new avenue for clinical trial recruitment that allows for a more positive experience for both investigative site personnel and potential participants.

KEY TERMS AND DEFINITIONS

Clinical Research: Research that directly involves humans or that utilizes materials from humans (such as blood or tissue).

Clinical Trials: A type of clinical research where individuals are assigned to intervention(s) to evaluate the outcomes.

Investigative Site Personnel: Teams of healthcare professionals who are led by principal investigators and are responsible for carrying out the protocol.

Participant Recruitment: Finding and enrolling the best-qualified patients in a clinical trial in order to answer research question.

Principal Investigator: A primary researcher who is responsible for conducting a clinical research study or trial as per the protocol.

Social Media: Web-based tools that allow for various types of communication or information sharing.

Social Networking: Websites or applications allowing individuals to interact with other users such as those with similar interests.

Why It Is Difficult to Disengage From Facebook

Sonda Bouattour Fakhfakh

University of Tunis El-Manar, Tunisia

INTRODUCTION

In many countries, social life has become heavily reliant on the use of Social Network Sites (SNS). The leader of SNS is Facebook (FB) with more than one billion monthly active users (Patterson, 2015). Founded in 2004 mainly by Mark Zuckerberg, FB was exclusively destined to the Harvard University. Later, FB began to expand to reach the entire world. The biggest demographic using the site is the 18-29 age range. The graduated adults from college are the leaders and women seem to use it more than men (Patterson, 2015).

The deeper intrusion of FB in the society and in the professional context has removed concern not to enhance connection but to break it. Many connected people begin expressing their willingness to be disengaged. They suffer from being invaded by technologies and steered to adapt their FB experience to an economic object (Van Dijck, 2013). Even though, they could not detach and continue to integrate FB into their daily lives they feel bored or busy. So, the power is already handed on those who could disconnect (Jauréguiberry, 2014). Thus, the main question that we try to give some responses to is: why it is so difficult to disengage from FB and alter its use?

We should note here that disconnection/disengagement is not the opposite of connection. It is obviously coupled with it and could not be understood without its existence. It involves the

choose-nots category by distinction with the have-nots and the want-nots, who consciously choose to not engage with FB partially or totally (Jauréguiberry, 2014). We consider disengagement as an approach of re-appropriation of FB use; a way of changing one's practices and a situation where the relation to and with FB is at risk (Karppe, 2014). When users will be faced by the choice to be separated from FB or individuals, attachment will be highlighted. Based on the attachment theory and the Actor Network Theory (ANT), we try to underline the nature and the quality of the attachment within FB network social structure. We then attempt to study the human/human attachment and the human/non-human attachment in order to border the disengagement phenomenon. Hence, the aim here is not to reject (or not) some formulated hypothesis but to develop a theoretical frame from the existing theories.

This analysis could help users as well managers and technology designers to understand how attachments to FB could impact people emotion and behavior. It answers to the serious preoccupation of the professional context about the permanent connection of their employees to FB and information technologies in general. This analysis could also help companies willing to implement disengagement measures to apprehend this choice from a relational perspective in order to get the implication of all users.

BACKGROUND

Preliminary Debate

While many studies emphasize the good effects of FB on users and its propensity to satisfy the need to belong and the need for positive self-presentation (Nadkarni & Hofman, 2012), some others draw its negative side such as the social media fatigue (Laumer et al., 2013) and the risk of dependence and addictions (Xu & Tan, 2012).

The question of whether the consequences of FB use are positive or negative is still debatable. However, it seems to influence / be influenced by the degree of user's engagement involved in/by/with FB (Karppi, 2014). If the disengagement phenomenon is related to the increase of connection (Sheldon et al., 2011), we should, at the beginning ask why people are so attached to the use of FB?

Amichai-Hamburger (2002) and Hart et al. (2015) assert that personality is a major factor in Internet use and in determining people's engagement causes and consequences with social media (here FB). Nadkarni and Hofman (2012) sustain that a high level of extraversion, neuroticism, narcissism, and low levels of self-esteem and self-worth are associated with high FB use. In two surveys of nearly 600 people aged 18 to 83, Hart et al. (2015) conclude that people who are more engaged with FB are higher in attachment anxiety and extraversion. However, they find that extraversion, neuroticism, and self-esteem were not as consistently related to user FB engagement.

Then, as FB is a virtual social network through which users create and entertain relations with each other, the attachment theory seems to be one of the leading theories for studying interpersonal relationships (Rom & Alfasi, 2014). Using FB seems to be influenced by how people successfully build relationships with their primary caregivers during their childhood period (Andangsari et al., 2013) which is successfully transmitted to adulthood (Hazan & Shaver, 1987).

Furthermore, we cannot treat the attachment of FB user only from the user perspective and so, from the study of human/ human relation. User practices should also be examined through the network conditions that empower them and through all things which can possess the user as much as he/she possesses them (Fenwick & Edwards, 2010). In fact, all the components offered by FB (messages, photos...) allow users to create/ destruct links, intensify/decrease ties and choose to interact with near/distant friends.

These complex associations, formed by human and non-humans entities, make the ANT (Latour, 1999) useful when studying FB user attachment. The identification of actors and their associations enables the understanding of their expectancies and objects and the appreciation of their role in the technology construction, adjustment and appropriation.

The Human/Human Attachment via FB Platform

Being connected with others is considered by the self-determination theory as one of the basic psychological human need. Nowadays, users compete to register the high score of FB friends/ likes/sharing regardless of their type of use to show their great socialization and famous. As the use of Internet, FB might be of particular utility for who are physically distant or who avoid face-to-face contact as they find difficulties to interact with others (Nadkarni & Hofman, 2012). It can so connect the absence (spatially) with the presence (Giddens, 2013), lower barriers to communication, enhance the control of time and space of interaction (Mckenna & Bargh, 2000), which provide a sense of security and belonging, the main elements of attachment.

The theory of attachment describes and explains the attachment styles of adult to close personal relationship (Hazan & Shaver, 1987). Within FB network, users are not simple individuals related to each other. They are relational individuals having, at the same time, different facets

and identities, which shape their representation (Dalsgaard, 2008) not only about themselves and the others but also about interpersonal loss, rejection, or abandonment. Founded on Bowlby's work on children's attachment to their primary caregiver, Hazan and Shaver (1987) distinguish between two dimensions (based on the internal working model) of attachment: secure and insecure. The latter is formed by three patterns (anxious, avoidant and disorganized).

Several studies have examined the relation between the attachment styles and SNS behaviors.

Despite the fact that some researchers have reported the absence of difference in SNS use (FB and Twitter) by attachment styles (Hansen, 2008), others have stated a significant dependence between use of FB and insecure attachment style (Hart et al., 2015; Oldmeadow et al., 2013; Rom & Alfasi, 2014). In fact, while the secure attachment people tend to be more comfortable with intimacy and independence when interacting with others (both on/off line), the insecure attachment people (the disorganized and anxious attachment styles) are significantly predictive of using SNS to avoid a more personal face-to-face discussion (Nitzburg & Farber, 2013). However, the disorganized attached people are likely to not feel intimate on these platforms and so they may express less demand for care on the SNS sites than the anxiously attached people. On the other hand, the avoidant attachment users show the opposite behavior of anxiously and disorganized attached people in using FB. They are reluctant to use FB. This could be due to their self-sufficiency and their lower involvement in building personal relationships over SNS (Hart et al., 2015; Oldmeadow et al., 2013).

So, anxiously attached people seem to be the most engaged on FB (Andangsari et al., 2013). The anxiety aspect of attachment refers here to the degree of concern above others' evaluation and approval. This type of individuals appears to be sensitive to positive feedback (likes, comments...)

which affects their feeling about themselves and intensifies their frequency of posting and updating status (Hart et al., 2015). Since they perceive others as available for their requests and problems, they are prone to greater importance to manage their self-presentation in order to get their attention because they anticipate and fear rejection (Hart et al., 2015; Oldmeadow et al., 2013).

However, and as noted by Rom and Alfasi (2014), by being active on FB use, anxiously attached people seem to perpetuate the same characteristics of social inhibition shown in the real world. If it is so, it may be possible then to understand why they cannot disengage. Disengagement would be assimilated to separation. When the anxiously attached persons are faced even to short separations, they could be profoundly disturbed and sometimes, this situation can lead them to panic states (Karen, 1994). So, they resist to this separation and could be so clingy that they may suffocate other by their claim of attention.

Indeed, if becoming more detached (but not less connected) during a period caused increased use of FB (Sheldon et al., 2011), it is likely to suggest, as argued by Bauman (2010), that users are becoming governed by the strong desire to be attached with others. If it is so, could we advance that insecurity, dependence on the emotions and acts of others and the obsessive behaviors to call on attention from the network and to not miss any information will be the cost supported by society?

"Numerous studies indicate that almost half of the human species can be classified as insecurely attached or insecure with respect to attachment" (Ein-Dor et al., 2010, p.123). Insecure attachment is not a pathology in itself (although it can be a major risk factor of disorder) and it is often the result of insecure parental figure (O'Brien et al., 2012). This figure is unable to give to her child the comfort and the security that she has not. Thus, a vicious circle will be created and the insecure attachment style would be perpetuated.

Yet some children spend eight hours per day with technology which is more than the quadruple of the number of hours recommended by the American Academy of Pediatrics. How will this digital generation grow, live and what attachment style will it have? If anxiously attached people perceive FB as the community to which they belong (Rom & Alfasi, 2014) and which provides them with security, so, these online relations will be the external sources that regulate their affection. This attention provided will thus be a reinforcement and reward to continue using FB (learning theory of attachment). Overall, the disengagement practices will be then more difficult.

The Human/Non-Human Attachment: FB Platform in Loop

Users wrongly believe that FB has only some specific known and pre conceived functions to realize (Latour, 1999). In fact, FB has a clear and simple functioning. Its features enable users to form, sustain or interrupt relations easier and without cost. That is why the degree of ease of use perceived by users is found to be deterministic for using FB (Nasri & Charfeddine, 2012). This conceptualization of technology (here FB) as an exterior thing to humans, draws from the acceptance models such as the TAM (Technological Acceptance Model) or the UTAUT (Unified Theory of Acceptance and Use of Technology). Regarding these models, humans decide to use the technology through their perceptions, evaluations and attitudes. Other external factors such as gender, culture or experience are also supposed to influence the relationship between humans and technology. However, technology is not just a material apparatus constructed by humans' actor to satisfy their interest in a particular context and on which they have power. It is also a product of their action. From this point of view, there is a dynamic interaction between actor, content and context which emphasizes the definition of technology by the ANT as a social construct.

By using FB, the actors are connected to their platforms... and this latter connects them (Latour, 2000) in such a way that they become united with FB (Karppi, 2014): they cohabit, co-evolve, co-act and have a mutual dependence (Brangier & Hammes-Adel , 2011). So, the inherent dichotomy between object/subject and the technological determinism are thus rejected and replaced by an equal ontological footing with one another (Graham, 2005) and a high level of technosymbiosis (Brangier & Hammes-Adel , 2011). Thus, when studying the relationship between the user and FB, the question is not the ability of the user as independent subject to manage or to accept/reject the technology as object, but the nature and the quality of the link that exists between them. Hence, the aim is to determine whether their attachment is bad or good, how it can condition the user's action (Latour, 2000). Overall, how user "enacts" with FB.

Based on the cognitive dissonance, Festinger (1957) argues that, when doing an action, the actor tends to avoid any feeling of discomfort by changing his/her way of actions. For example, the disliked object when associated with the liked person/content becomes less disliked. Applying this principle of congruity, even if users dislike their use of smartphone or computer screen and aim to disengage, their attachment to what is shown, heard or read through this referential interface prohibits them to do so. The face-to-face is increasingly replaced by this active interface which becomes users' eyes, hearing and even by which they smell and touch things.

This role is also played by the FB software. In fact, FB communicates with users and replaces their physical absence by sending a heard and seen signal to inform about interaction. It also acts like an extension of the human memory when reminding them of the birthday of their friends or of their participation in events. Moreover, when users logs on to FB for the first time, an affective bond seems to be constructed in such a way that when they attempt to quit FB, an emotional request will be appeared showing the potential

loss of not only the online relations but the offline also (Karppi, 2014). Users' response will be then distracted and they will be worried about the implications of this request. These links, described by Licklider (1960) as a symbiosis, show a direct relationship and a mutual dependence between FB and users and underlines that FB is not just an object but a partner.

Nevertheless, this is the visible category of the iceberg. There are hidden facets that mask the users' "interactive loneliness" (Lipovetsky, 2006) and their "accepted isolation" (Guillaud, 2011). The molecular forces, which work behind the visible side, invite users, unconsciously, to interact (Sampson, 2012), to navigate only where friends or friends of friends had navigated (Guillaud, 2011) and to remain into a personalized "filter bubbles" (Pariser, 2011) in which pertinent information predicted by the EdgeRank algorithm from user's profile will be selected (Taffel, 2015). This algorithm masks the messages that are incongruent with the background or the political orientation of a given user, hides the status less liked by him/her and even deletes FB's accounts of revolutionary activists (as it was done in Tunisia when Ben Ali was President) (Lindenberg, 2011). So, it allows a preferential attachment in such a way that "the rich get richer and the good get better". Consequently, the information received by users is not objective nor it is completely randomized; and the social link that they, mistakenly, believe to maintain is selected and not independent. This way of FB commodification and algorithmic agencies could be described as being "anti-social" (Taffel, 2015), unethical and lack transparency (Pariser, 2011). Furthermore, FB transforms the users' profile, shares, like (even the past forgotten ones), friends and their amount of time spent connected on the platform into an economic opportunities by delivering information to the relevant commercial sites which personalize ads and shape user relation and behavior. Indeed, FB forces sometimes the users to accept the violation of certain laws which were conceived to protect their private sphere before allowing starting a service. In some, FB structure

orients the action to a preferential way and tries to guard this "merchandise" by manipulating emotion, behavior and past memories.

Overall, through the FB technical platforms, affective relations and strong ties with users are created. By the selection of who they should contact, view and share, FB gives the unaware users what they want to read, reinforces their self-presentation and meets their needs. This relation will make the disengagement difficult and a painful choice.

When FB is inaccessible (voluntary or mandatory), users could express distress/anxiety/awkward as if they will be separated or anticipated separation from an attachment figure. This negative feeling seems to be also expressed with the mobile phone, an interface that can allow FB connection (Lee and Katz, 2014).

Hence, if the hardware has contaminated all physical space, the software has passively affected the users' participation by analyzing their habits and their desire (Karppi, 2014). So, Software influences individual or collective behavior as do subjective norms and social influence. Based on this analogy, users seem to conform to the influence of FB platform as to the pressure of "normal" society to continue to be connected. To disengage will be thus regarded as abnormal behavior and will show an uncared feeling of others loss.

FUTURE RESEARCH DIRECTIONS

This investigation has FB as unit of focus. So, generalizing this analysis into other SNS is limited although some facets could be shared (Hargittai, 2008). Additionally, other variables could influence relations regarding FB use. While some studies indicated the relation between gender differences and parental education in FB use (Hargittai, 2008) and the attachment styles, others, have stated the influence of age on frequency of SNS use (Nitzburg & Farber, 2013) as well as differences across cultures (Nadkharni & Hofmann, 2012). Moreover, Stieger and al. (2013) show that people who disengage from FB are especially those who

are more worried about privacy, have an average age of 31 (those who still using Facebook has 24 years old), are men, have fewer friends and they are (slightly) more hooked on the web. Future studies could take into account these variables and test their relations with the human/human and human/non-human attachment. They could also initiate some FB disengagement practices in a voluntary or mandatory context and evaluate their relation with user attachment styles as well as the “translation” process with regard to the technology mediator. Besides, considering the impact of culture, it is possible to test the influence of people who are orally oriented (i.e: Arab and African countries) on the FB disengagement.

CONCLUSION

The aim of this analysis is not to determine whether users are independents from or slaves of FB, but rather, how attachment shapes the FB and the users, could enable or disable users’ actions and could enhance/constraint their rational/irrational behavior. Surely FB platform allows people to keep in touch with others and makes new relationships more easily accessible. However, the nature and quality of attachment that it maintains seem to transform the relation human/human and human/non-human, which requires more investigations and raises more awareness.

Our analysis shows that the attachment could be a major predictor of FB use. In fact, anxiously attached users are more inclined to find difficulty to disengage since they receive the attention and reassurance required from the online community. Besides, FB platform keeps users in touch thanks to its features but also its affective interaction. However, these relations are not equal. There is an exchange asymmetry about information at the expanse of users and a manipulation of their cognition, emotion and behavior. Since 1964, Ellul argued that moral considerations between technique and its use cannot exist in the new

social order. Even though, the users, unworried, continue to be attached.

Through disengagement, it would be possible to show the hidden facets of FB platforms and to select what attachment should be preserved and what should be removed or remodeled. Based on the rational choice theories, human actors have the ability to distinguish between the costs and the benefits of their action guided by their personal interest. Then, more awareness about the misuse of personal data by FB for commercial goals should enhance the degree of care and limit the degree of openness of single users.

It is delusional to believe that it will be a full disengagement (Jauréguiberry, 2014). But, some emergent disengagement practices could be applied (use of technical filters, rational click on like function...) which can be helpful in optimizing users/platform’ relationships and changing the rules of the FB game.

By reference to the learning theory, resistance to disengage results mainly from the user’s operant learning experience. If so, the nature of attachment could be relearned and the FB use re-appropriated.

KEY TERMS AND DEFINITIONS

Actor Network Theory (ANT): It is an approach that treats an object as a social construct and assumes that it can act as the human in a network.

Anxiously Attached Person: It refers to the degree of concern exhibited by a person over others' evaluation and approval. It is manifested by an excessive need for attention and reassurance.

Attachment Theory: It presents different styles of attachment that have been built in the childhood period and transmitted to the adulthood. These styles can explain some aspects of the attachment to Facebook and the consequences of disengagement perceived as a separation from caregiver's figure.

Disengagement: It is a way of changing one's practices of connection and an approach of re-appropriation of technology/FB use.

Facebook: It is a SNS which allows a variety of free ways of communication for multiple users and use but with an asymmetry exchange of information and a manipulation of users' cognition, emotion and behavior.

Human and Non-Human Attachment: It is a relationship between human and material generated from the ANT. These two actors are considered to have an equal status until they enter into association within the network.

Social Network Sites (SNS): They are sites that provide possibility to interact with others but which may impact the interpersonal relationships, the human well-being and behavior.

Community Science and Technology and Its Meaning to Potential Requirement

S

P. K. Paul

Raiganj University, India

A. Bhumali

Raiganj University, India

INTRODUCTION

Community Science and Technology (CST) is an emerging concept as well as a broader domain that deals with various aspects of community and societal development. Community Science and Technology may be deemed as subject responsible and dedicated for community and society development. This domain talks about Science and Technology and its development for society and community. On other hand, Community Science and Technology (CST) may be expressed as a domain of Science, Technology, and Engineering responsible for social and community development. CST may come as a full-fledged education programme which should talk about community. On the other hand, it is a domain with focus of community and side by side other domains. Chapters mentioned are community science its meaning, role, values with special reference to emerging and possible domain. Community Science and Technology is actually an emerging concept and it's a domain which is directly and indirectly related to the community or society or development studies (or related subjects) (Avgerou, 2003; Paul et al, 2012a). Information Science is an interdisciplinary domain and responsible for information vis-à-vis technological solution with social science perspective. And thus the domain may be treated as a domain of Community or Social touch or more clearly, a domain of Community Science and Technology.

BACKGROUND

CST is a conceptual domain dedicated to societal development through proper science and technological tools (see Figure 1). Community Science and Technology may be brought as both, individual course of study or may be an individual subject with CST flavour. If it is a full-fledged CST programme then it may deal with several aspects of Community including its nature, role, diversity and side by side valuable for expressing the tools and techniques responsible for community or society and ultimately for its development today. Many aspects like virtual community, social network, and community development may also fall under the CST. Science and Technology are the main sources for the development whether it is industry, communication, education, governance and others. Such development and modernization of society is also possible with better and healthy Community Science and Technology related applications. The main background of this chapter includes but not limited:

- To find out about and learn on Community Science and Technology including its basic nature and characteristics.
- To learn and find out about Community Science and Technology as a stakeholder of development and modernization.
- To know about future potentiality of CST related programs as an academic specialization courses.

Figure 1. The basics of community science and technology

- To draw an exact picture and possibilities of CST program related to Community Science and Technology and its development.
- To find out Service Science and Community related aspects in Information Sciences and Technology.
- To design and development of Information Science related curriculum focused with Community Science and Technology gradients or specialization.
- To find out main problems and challenges of MSc- Information Science/ Information Sciences and Technology course with CST flavor.

This conceptual vis-à-vis policy study has been undertaken by the several tools and methods. Among others, review of literature is the important source of information. The web review, study of existing Community Science and Technology related programme has also played an important role to do this research work. It is a fact that material in the form of paper or chapter on Community Science and Technology is very limited. Hence web review has been undertaken to learn about the term and emerging concept. Role of specific subject to the community like computer in community, communication in community, energy

informatics and management in the community and others critically analyzed and thus huge literature has been consulted and indirectly used to prepare this study.

COMMUNITY SCIENCE AND TECHNOLOGY (CST): BASICS WITH POSSIBLE NOMENCLATURES AND FUTURE POTENTIALITIES

Community Science and Technology or CST is a growing concept and may be deemed as a broad discipline with interdisciplinary nature. It is actually a combination of many academic domains and fields. These fields may be from community, society, science, technology, engineering and some related facets. CST is dedicated or more clearly responsible for healthy application and utilization of science, technology and engineering fundamentals to the service sector, industries, commercial hub, governance, and education as directly or indirectly to the community and its development. In other sense Community Science and Technology may be defined as Applied Science domain having societal or humanities touch. CST in other way may be viewed as a domain for the community, of the community and by the community (Corneo G., Jeanne O, 1998 and P

K Paul & Sridevi, 2012b). Today many domains are indirectly connected with several aspects of Community or Society (see Figure 2). Thus CST is also there, indirectly.

Importantly, Community Science and Technology (CST) is responsible for community and overall societal development as it deals with community aspects and direct utilization of science and technologies in the community. The frequent community development is no doubt responsible for sophisticated social development. Community Science and Technology (CST) may be treated as the domain which has direct or indirect relationship with community or development or comes as service science nature (Lucas R., 1988 and Paul, PK, 2012a). Agriculture, environmental science, fisherman, food and nutrition, horticulture— are indirectly acted as community development domain and thus these subjects may be treated as a Community Science (or Community Technology in the some cases). For example the domain of food and nutrition is a domain responsible for development of healthy nutritional infrastructure building and as it helps in better product building etc. Thus it builds nutritional utilization properly among the community or society (La Porta R,

1997) and in this sense it may be deemed as a Community Science and Technology.

Still Community Science and Technology is as full-fledged domain or an academic domain not much popular or available in the universities around the world. Though it is possible to design and develop Community Science and Technology domain with BSc/MSc or in other related program. The domain may be treated as Social Technologies or Social Engineering. The basic and possible nature and gradients of Community Science and Technology may be related on the following aspects:

- Community and its nature.
- Stakeholders of community development.
- Key Issues on Community.
- Development of community development.
- Community structure and formation.
- Diversity, Development and technologies.
- Stages of community and rural development.
- Social Psychology and Promotion.
- Business, Economics and Society.
- Rural Development and Allied Technologies.

Figure 2. Some community science existences

- Social Inclusion and Standardization.
- Stakeholders of community.
- Science for community and its allied branch.
- Technology for Community and Social development.
- Social Engineering and Community Management.
- Computing for society and some other domain.

However, Community Science and Technology (CST) may also bring with some other domain specialization. For example, food and nutrition science is very much related with community and society as people are the largest stakeholders of food domain. Thus here it is possible to offer Community Science and Technology (CST) touch or flavour in Food and Nutrition science and the program may be offered either as BSc/MSc-Community Science and Technology (Food and Nutrition science) or there may be potentially of offering BSc/MSc- Food and Nutrition science (Community Science and Technology). Here in this structure 'Food Science' as well as the 'Community Science' (or CST) may be included for wider benefit and advantage of the community. Ultimately, this type of program is helpful to use the Food as well as Nutrition to the door step of the community. Here academicians may be aware about various topics as well as some aspects of food and nutrition for the complete development. Their integration in CST is also an important issue and helps in relationship with community or society. Hence indirectly, for specialization of BSc/MSc- Food & Nutrition Science (Community Science) the above mentioned (bolded) aspects of community science may be included.,

These subjects may be (but not limited to the) Family welfare, Community Medicine, Community Nursing, Rural Development, Mass Communication, Micro Biology, Environmental Science, Sustainable Development, Communication Science, Ecology, Population Studies, Defense Studies, Himalayan Studies, Geo Information

Science, Strategic Studies, Food Science and Nutrition, Dietetics Studies, Agriculture, Horticulture, Public Administration, Information Science, Information Studies. Thus the nomenclature may be offered as follows:

- BSc/MSc— CST (Home Science).
- BSc/MSc— CST (Nutrition Science).
- BSc/MSc— CST (Food Science).
- BSc/MSc— CST (Textile Science).
- BSc/MSc— CST (Renewal Energy).
- BSc/MSc— CST (Agricultural).
- BSc/MSc— CST (Environmental Science).
- BSc/MSc— CST (Community Computing).
- BSc/MSc— CST (Social Computing).
- BSc/MSc— CST (Community Informatics).
- BSc/MSc— CST (Communication Science).
- BSc/MSc— CST (Information Science) and similar one.

In the field of Humanities the Community Science aspects may be included and may offer as an area of study or specialization like:

- BA/MA—CST (Public Administration).
- BA/MA—CST (Defense Studies).
- BA/MA—CST (Himalayan Studies).
- BA/MA—CST (Strategic Studies).
- BA/MA—CST (Sustainable Development).

Though apart from Science stream these programs are also possible to offer with Engineering and Technology domain but, as community is an interdisciplinary domain and this is related with some other aspects of community and humanities thus it is better to offer as Science stream (BSc/MSc). It is important to note that depending upon academic structure of the countries, option need to open-up for other degrees like- BS/MS/BE / ME/MTech/BTech. Some science characteristics is actually in built in Community Science and

Technology and this some other nomenclature are also possible to use like Social Computing, Community Informatics, Social Informatics, Communication Science, Information Science, Informatics and so on (Furuholt, B., & Kristiansen, S. 2007 and Thompson, M. P. A. 2005).

Though research program and project work funded by several agencies and in the degree programs may be an interesting tool for the development of Community Science and Technology and allied domain. It is valuable to note that though the nomenclature CST is comparatively new but the concept is old and already exists and thus research activities leading to Project Work/ PhD or higher are possible in this domain with existing setup.

COMMUNITY SCIENCE AND TECHNOLOGY (CST) AND ACADEMICS

Community Science and Technology (CST) may get the wider possibilities and benefit by universities and particularly from the related departments. Here the community aspects related departments may choose community knowledge gradients in their course curriculum for direct utilization of that particular program like if computing/ Information Technology program includes some community related aspects then social and community interaction is directly possible.

In health sciences, some domains have been arrived like community medicine, community nursing. Thus universities may establish separate departments / schools on Community Science and Technology (CST) or may include Community Science and Technology (CST) in some allied or related subjects/ domains. Research and development activities are possible in the areas of Community Science and Technology (CST). Even separate university may be established on Community Science and Technology (CST) with wide range of subjects having connection with

Community Science and Technology (CST). Thus full department may be established on Community Science and Technology (CST) and other domain as listed in the figure for creating better community based applied science domain (Paul, P.K., 2013a, c).

INFORMATION SCIENCES AND TECHNOLOGY (IST) VIS-À-VIS COMMUNITY SCIENCES & TECHNOLOGY (CST)

Service Sciences are the domain which are directly and indirectly helps in service offering and its promotion. Due to this hospitality nature, Information Science is also treated as a service science and in some cases service technologies. Information Science programs are available with several levels and out of these levels MSc-Information Science is considered as most valuable and popular around the world. Ultimately better information transformation leads economic development (Chattopadhyay, P., 2014 and Paul, P.K., 2012b).

Though the basic differences of Information Science with other domains like Information Technology, Computer Science, Computing Engineering is that Information Science is far more related with nature of Science and aspects on behavioral Information including its proper management and uses for the people or communities. Other hand, IT/Computing is mainly responsible and dedicated to the technological applications.

Community Science and Technology (CST) is a domain and a field which has relationship with the community and society related aspects. As an academic program the nomenclature of Community Science and Technology (CST) not gains popularity and thus very limited numbers of universities are offered Community Science and Technology (CST) as Bachelor/ Masters Degree (Paul, P.K., 2013b). In academic community some subjects gaining with Community Science atmosphere (or for the community or society) like:

- Home Science.
- Nutrition Science.
- Horticulture.
- Agriculture.
- Food Science and Technology.
- Textile Management.
- Rural Development.
- Renewal Energy.
- Agro Business Management.
- Urban Planning and Development and some other subjects.

These subjects are responsible for the community development as well as building and obviously societal progress in many ways.

Community Science mainly talks about development, modernization and up gradation of community and society through proper use and utilization of science and technological subjects. Community Science and Technology (CST) may also be treated as subject *of* the, *by* the and *for* the community.

CST as a course and department name available throughout the world. In India also, IEST, Shibpur has the unit –School of Community Science and Technology (SOCSAT) and some other university running programs on Community Science and Technology (CST) like- Community Medicine, Community Nursing, Community Informatics and so on. The MS University, Baroda offers a full-fledged Degree on Community Science (Corneo G., Jeanne O, 1998 and Paul, P.K., & Dangwal, K.L, 2012c).

CURRICULLUM OF INFORMATION SCIENCE: CST POTENTIALITY

Information Science is an advance field of study and practice responsible for several information activities such as information identification, collection and selection and their proper dissemination or delivery. The similar name of Information Science *with* Information Technology/ Computer

Science denotes that both are same domain but practically there are many differences between two. First of all Information Science is an Information domain whose main aim is restricted on how and whom information is needed to deliver for the common people or sector or industries by information systems designing. On other hand, Information Technology or Computer Science is responsible for design and development of computing systems. IS and its increasing interaction with the Technologies lead the newest nomenclature Information Science and Technology (IST).

The advancement of Information field changes Information Science many ways and several technologies as well as tools have been added which includes the Database Technology, Multimedia Technology, Communication and Networking Technology, Information Retrieval Systems, Web Technology and HCI in the IS knowledge stack. Thus the traditional information collection and dissemination systems has been changed and come as field with IT and Technology cluster. Still Information Science talks about information and its various natures like collection, selection, organization, nature and behaviours of information, information ethics and other facet and simultaneously on uses and applications of IT and Computing for better information practice.

Thus, Information Science is actually a science about information and its various facets. A basic M. Sc curriculum of Information Science in European and Indian style leads two year duration and in some cases it comes with specialization of Information Literacy, Information Management, Communication and Networking.

This chapter plays an attention on ‘Information Science and Technology’ and on ‘Community Science and Technology’ atmosphere. Now, let’s see about the curriculum and gradients of Information Science. A basic IST curriculum is actually integrates with computing and Information Studies, Management Studies, Information Technologies, Cognitive Sciences and some gradients /papers like:

- Information and Knowledge/ Information Society and Culture/ Information and Knowledge Management/ Knowledge Organization (Cataloguing)/ / Knowledge Organization (Classification)—as Information Studies related gradients.
- Database Management Systems/ Networking Technology/ Communication Technology/ Multimedia and Graphics Technology/ Information Retrieval Systems/ Search Engine—as computing and Technology related knowledge gradients.
- Management Basics/ Management Information Systems/ Organization and Business Informatics/ Information and Organization/ Knowledge Management—as Management related knowledge gradients;
- Cognitive Science/ Psychology and Information/ Human Computer Interaction/ Usability Engineering and related areas as Social Science related domains.

Hence, whether it has included Technological paper or Information, the Societal and Business related touch has been lying with IS/IST. Importantly, Information Science and Community Science based curriculum is proposed here as 2 years of duration with 4 semesters. Here each semester holds 6 papers of 4 credits each credit is actually education for 10 hours of duration (*see Table 1*).

Here all the semesters have been dealing with either technology or information centric paper but closely related with the society or community.

The proposed syllabus of MSc-Information Science (Community Science) presented here as Information Science and Communication Technological integration. Here gradients have presented based on aspects of information, computing and side by side community and society aspects. Community and Information Science integration may be treated as a new domain of Information Science or as a new flavour of Community Information Science.

This is mainly responsible for the design and development of Information Systems and Information infrastructure for the community need. Here directly information and technological uses on community related matter and field are provided with importance. It may be a healthy tool for societal and community development. In the third semester one internship program has been proposed due to its impact. Internship may be carried out in the technological settings, information dealing entities or social sector (such as NGO, Community health point, Telemedicine centre and so on). The fourth semester is proposed to undertake dissertation of around 18-20 credit. The dissertation may undertake as a project to solve a problem or may also undertake an Internship (Industrial/ Research) of around 180-200 hours at any approved and allied settings of the program interest.

Table 1. Showing the proposed structure of MSc-information science with community science flavor

Semester-I Information and Knowledge Information Society and Development Information Organization-I Computer Basics Community and Community Science Societal Development	Semester-II Knowledge Organization-II IT Application Networking, Information and Communication HCI and Usability Engineering Knowledge and Business Information Applications –Community and Industries
Semester-III Community Informatics- Development and Design Advance Computing and Community Informatics Societal Development, NGO and IT Project or Dissertation Internship Networking and Community	Semester-IV Dissertation (18-20 credit) Or Internship (Industrial/Research) Of 180-200 hours

Figure 3. Depicted information science and role of community science for its up-liftmen

CHALLENGES AND FINDINGS

Practically each and every activity has some challenges and as far as this topic and research is concerned the following points are important:

- CST still not recognized as an academic field or with degree program but got recognition as a concept and constitutes some interdisciplinary aspects like Nutrition, Community Medicine and others. And thus in academic world long destination is waiting for.
- CST is not a subject like physics or computer science it is a big interdisciplinary cluster and aspect. And thus building a real curriculum and healthy implementation and availability of HR is an important challenge.
- CST is an applied science and interdisciplinary in nature and it has wider connection in social and humanities domain and thus proper collaboration of Science department (such as for CST with Information Science need to collaborate

with Management Science) with humanities need to undertake.

- Information Science/IST has higher possibilities as community information nomenclature building domain and removing digital divide.
- The proposed curriculum is based on near about 65% of information and technological gradients and remaining are deals with community, society and development studies including business studies. Thus the seeker and providers both need interdisciplinary approach.

RESEARCH DIRECTION AND SUGGESTION

This chapter is the outcome of possible integration of science, technologies with humanities and management and thus following fact and step may be undertaken—

- Community Science is required to start as an academic program and there are possi-

bilities exist to offer Information Science as specialization. Though the vice versa or offering CST specialization is also possible in the IS/IST program (Paul, P.K., 2013c).

- CST may include in the course catalogue of universities for sophisticated development and utilization of education and academic program. Here, individual level of programs and courses may be designed in future for the betterment of technology and humanities or more clearly improving digital humanities.
- CST gradients need to include in other domains of interest and thus, there is a potentialities to find out and possible inclusion of the domain in future research or study.
- A center/ schools need to establish in each university and other institute of academics for interacting various departments.
- Workshop, seminars need to conduct on various aspects on social science and technology and for its further development.
- It is possible to offer Community Information Systems merging or collaborating some related departments like IT, Information Science, IST, Management with social science related department like social work, societal and rural development.

CONCLUSION

All about, 'community and we' and CST is responsible for better community and social development— directly and indirectly. The indirect relationship is useful with the electronics, agriculture or environmental sciences for the community or society. There is an urgent need for development of CST focused academic program. Or in other words utilization of these programs may bring educational, commercial, business, governmental development and development of these aspects ultimately can brings all round development.

Community and rural development play an important role for overall societal development. Information is treated as power and important gradients for overall information infrastructure and technological infrastructure development. The society many ways can grow with the integration of information and community aspects. Thus here several things are possible from academic and professional side for the development and modernization of CST as a discipline and Information Science as Computer Science field. In the developing countries still Digital Divide is an important and challenging issue and thus such problem may be minimized as much as possible by the possible integration of CST as a domain and CST flavour in other domain.

KEY TERMS AND DEFINITIONS

BSc: It is a University Degree or Higher Degree. Normally is treated as graduate program in the European countries and other followers. Normally the program offers with 2-4 year of duration.

Community: It is actually a social unit of any size that shares common values; however he embodied or face-to-face communities are usually treated as small, larger or more extended communities such as a national community, international community and virtual community are also studied.

Community Science: It is a conceptual domain dedicated to societal development through proper science and technological tools. Community Science may bring as both, individual course of study or may be an individual subject with CST flavor.

Developing Countries: It is the countries which are economically and socially trying towards betterment by economic and social maintenances and proper policy implementation.

Digital Divide: It is the concept and aspect of disparities of Information Technology product uses among the common mass. More clearly, still in the society some are having access and condition of using several IT product and some are not able to use due to economical and social status.

India: The Republic of India is located in South Asia. Virtually it is the seventh largest country by area and most importantly second most popular

with 1.2 billion people. Many religions originated from here and some of them are Hinduism, Buddhism, Jainism and Sikhism.

Information: In general processed data is called Information. Though, clearly Information as a concept has a diversity of meanings, from everyday usage to technical settings. Generally speaking, the concept of information is closely related to notions of constraint, communication, control, data, form, instruction, knowledge, meaning, mental stimulus, pattern, perception, and representation.

Information Science: Information Science is actually a discipline of disciplines. It has come from the subjects and fields which are information, information services, information activities and digital information.

Interdisciplinary: Connection between some subjects irrespective of domain and direct and indirect connection with main facet or sub field. Such as Bio Chemistry, Information Sciences, Community Sciences.

Internet Community: It is a Group of people are complex, in ways that make those groups hard to form and hard to sustain; much of the shape of traditional institutions is a response to those difficulties. In the Internet Community, an online community builds weaker bonds and allows users to be anonymous.

MSc: It is a University Degree or Higher Degree. Normally is treated as graduate program of advance level in the European countries and other followers. Normally the program offers with 1-2 year of duration.

Science: It refers to this body of knowledge itself, of the type that can be rationally explained and reliably applied. In the West during the early modern period the term “Science” and “Natural Philosophy” were sometimes used interchangeably to refer to the study of natural phenomena.

Service Science: It is a domain of interdisciplinary nature dedicated to serve or more clearly services to the wide scale such as organization, institution, community and so on.

Technology: It is the collection of techniques, skills, methods as well as the processes which are used in the production of goods or services or in the accomplishment of objectives, such as scientific investigation. Technology term and concept can also be the knowledge of techniques, processes.

UGC: University Grants Commission is the main regulator of Universities of India, Including Central, State, Private and Deemed and other institutes which are listed and granted funds etc.

Financial Inclusion, Content, and Information Technologies in Latin America

Alberto Chong

Georgia State University, USA & Universidad del Pacifico, Peru

Cecilia de Mendoza

Ministry of Production of Argentina, Argentina

INTRODUCTION

Information and communication technologies are becoming widespread all over the world, changing the way people interact, consume, produce and learn. Personal computer, Internet, fixed, and mobile broadband penetration are all trending upward in Latin America, although the overall penetration still levels remains low (ITU, 2013a, 2013b). ICT have brought truly new and innovative possibilities to developing countries and Latin America has not been the exception. Here are just a few far-flung examples. In Honduras, farmers receive market price information via SMS (Pineda Burgos, Agüero Rodríguez, & Espinoza, 2010), in Colombia, coffee workers in rural areas can receive and make electronic payments (Chong, Galindo, & Pinzón, 2011); in Bolivia and Peru, individuals receive text messages to remind them to save (Karlan, McConnell, Mullainathan & Zinman, 2010); in Chile, financial literacy campaigns can be delivered with the help of information technology (Hastings, Mitchell, & Chyn, 2010); in Peru, researchers take advantage of the role of new media in order to increase savings among the poor (Chong & Valdivia, 2016); in Bolivia, public officials use computers in order to reduce discrimination (Chong & Yanez-Pagans, 2016).

Policymakers and academics agree that cyber-instruments can be beneficial for economic and social development, yet virtually no systematic or solid assessment exists on the mechanism and impact of ICT on the welfare of people. The

lack of adequate data to better understand basic problems in development economics has been a recurring problem for decades. A number of the interventions summarized in this chapter avoid this problem by relying on a set of field experiments—actual projects that were tested in the field—in several countries in Latin America and the Caribbean. They rely on randomized experiments, or randomized controlled trials (RCTs), which are increasingly used in formal empirical research in development economics. In a RCT, individuals or communities are randomly assigned to different “treatments” – different programs or different versions of the same program. Since the individuals assigned to treatments are exactly comparable (because they were chosen at random), any difference between them is the effect of the treatment. One of the reasons RCTs are becoming a widespread method of testing is that they help identify the specific variable that may have caused the particular result under investigation. RCTs help to disentangle a particular outcome from the various factors that may have caused it. Thus, the method can have many uses in policy-relevant applications.

With adequate policies in place, governments can take great advantage of cyber-instruments for development. But it’s important to keep in mind that greater access to these tools won’t bring about development on its own. Countries must also focus on how these tools are used. The trials presented in this chapter show that in order for cyber instruments to contribute to development it

is necessary to take into account equally crucial elements, such as human capital, the institutional context, and the policy goals of governments. In many cases, adopting the latest technology will not necessarily generate the best development outcome if, for example, the population lacks the basic literacy skills to use such technology properly. This chapter calls for countries to invest in infrastructure, regulation and human capital to improve their capacity to benefit from greater access to technology. And it recommends that governments systematically evaluate the impact of ICT on projects.

BACKGROUND

The earliest scholars studying the link between Information Technologies and development are Professors L. Roller and L. Waverman, who studied the overall impact of cyber-technologies on economic growth. Their most influential publication investigates how telecommunications infrastructure affects economic growth, finding a significant positive causal link, especially when a critical mass of telecommunications infrastructure is present (Roller & Waverman, 2001).

Current leading scholars have dealt with several interventions and cyber-behaviors in South Asia and Africa. To cite some of the most relevant work, Professor Robert Jensen (2007) showed that the adoption of mobile phones by fishermen and wholesalers in Kerala, a state in India with a large fishing industry, was associated with a dramatic reduction in price dispersion, the complete elimination of waste, and near-perfect adherence to the Law of One Price. Professors Banerjee, Esther Duflo and others (2007) evaluated a program in India in which fourth graders shared the use of software for two hours a week to improve learning in mathematics. The authors revealed that the program produced impressive results in learning, although the effect was temporary and most gains faded away a year after the program ended.

For the case of Latin America, the available evidence has been based mostly on anecdotal cases that describe success stories, but provide little solid empirical evidence on the link between cyber-behaviors and purported related gains in productivity and welfare. In evaluating the impact of information and communication technologies—in Latin America and the Caribbean and elsewhere—a critical problem has been the lack of reliable data that may allow the specific role of a particular ICT tool to be isolated. While some advances in data collection have been made in recent years, this central issue persists for the most part. More recently, Chong (2011) made one of the first efforts to provide systematic evidence on the role of ICTs on development outcomes in the region. In more recent years, several researchers have further studied the role of ICT on development outcomes and in particular, have paid attention to financial issues and in the fact that ICT as tools, need primarily good content to be effective.

CYBER INSTRUMENTS AND FINANCIAL INCLUSION

As financial sectors develop, financial inclusion increases and income inequality diminishes. Despite the benefits of establishing links with the financial system, very few households in the developing world use such links. On average, only 35 percent of Latin American and Caribbean households have a bank account—a very low percentage compared to advanced economies, where no less than 90 percent of the population has this type of link with the financial system (Demirgüç-Kunt, Beck, & Hohohan, 2008).

Households can enjoy access to financial services through several types of technological improvements. The development of the Internet has allowed many households across the world to exploit the benefits of online banking, such as paying utilities or transferring money. The possibility of banking through cellular phones is a

very popular and expanding avenue in the financial world. It can help diminish financial exclusion by offering services to low-income groups that have access to mobile telephones but not to financial services. ICT can also be a very useful tool to provide information to help people make better financial decisions.

Mobile finance has been boosted by the strong growth of mobile phones throughout developed and developing countries. Worldwide, people have more cell phones than bank accounts, and Latin America and the Caribbean are no exception (World Bank 2010). There are many reasons why people do not have bank accounts. Having a telephone will not change important underlying factors determining that decision—but having a cellular phone can solve one issue that limits financial inclusion: limitations in the brick-and-mortar infrastructure of a financial institution. In many places, reaching the poorest is a geographical challenge. Imagine a coffee farmer who lives high in the Andean mountains in Colombia. Despite producing one of the most valued commodities in the world, this farmer would find it very difficult to be linked to the financial system. There is little incentive for the coffee grower to have a bank account, and there is even less incentive for a bank to open an office in a remote area for a handful of coffee farmers. Technology can break this constraint and align the interests of both parties.

Using mobile banking services could vastly improve this farmer's lifestyle. He probably has a cell phone, since Colombia's coffee industry has joined the growing trend of merging cell phones with financial services. In 2009 a pilot to provide financial services to the coffee-growing community was promoted by the National Federation of Coffee Growers of Colombia, the Inter-American Development Bank, cell-phone provider Telefónica, and the Banco de Bogotá, a large Colombian bank. The mechanism used is a very straight forward one in the mobile banking community.

The coffee growers sell their coffee at the nearest cooperative. The proceeds of the sale

are deposited in a bank account that each coffee grower has opened at the bank—an account that they can fully manage through their cell phones. Coffee growers can purchase supplies and production inputs at local facilities by accessing their bank account with their cell phones. This not only eliminates the risks of managing cash, but significantly reduces transaction costs by saving coffee growers a trip to the nearest town to purchase goods and services.

REMINDERS INCREASE SAVINGS

Cell phones can be used not only to provide financial services, but also to encourage certain types of behavior, particularly to help people exercise greater financial discipline and self-control. An example is saving. People usually promise themselves that they will set aside money until they achieve a certain goal. However, these promises are often broken because people postpone savings to the future, turn a blind eye to future needs, or choose current over future consumption.

To date, Latin America and the Caribbean has been moving relatively slowly to exploit technology to foster financial inclusion. Nonetheless, many pilot projects have taken off and researchers in the region are beginning to take stock of the lessons learned (Chong, Galindo, & Pinzón, 2011). A recent study by Dean Karlan, Margaret McConnell, Sendhil Mullainathan and Jonathan Zinman explores the impact of reminding deposit holders about commitments on how much money they want to save and how often they should make deposits. An experiment was carried out in Bolivia, Peru, and the Philippines in which specific banks sent messages to their clients to remind them about their savings commitments. The reminders have a positive and significant impact on savings, compared to clients who also made saving commitments but did not receive the reminders. On average, the people that received the reminders achieved their deposit goals 3 percent more often and were able to save 6 percent more.

Karlan et al show that reminders change intertemporal allocations and improve consumer welfare by linking future expenditure opportunities to today's choices. In the authors' words, they mitigate "attentional failure:" that is, inattention to future consumption opportunities.

The experiment conducted by Karlan and his team varied slightly from country to country. In each experiment, individuals opened a bank savings account that included varying degrees of incentives or commitment features designed to encourage them to reach a savings goal. Some individuals were randomly assigned to receive a monthly reminder via text message or letter, while a control group received no reminder.

In Peru, the researchers worked with a state-owned bank, Caja de Ica, and offered a new product called Plan Ahorro to clients. The clients selected a time frame to achieve a certain savings goal (6 or 12 months) and a minimum deposit to make each month. If the client reached a goal, he or she was rewarded with an 8 percent interest rate, twice the regular interest rate of the savings product offered. A fraction of clients were selected to receive reminders. Some reminders included the goal and others did not. The wording changed in some reminders to emphasize a gain from savings or a loss from failing to save. Late reminders were also sent. Cell phone coverage in the area was low, so the bank sent the reminders by mail. Two additional treatments were tested. One randomly sent a letter to some people in the reminder group that focused on their particular goal (in addition to containing the boilerplate reminder). Another treatment independently and randomly offered clients a gift upon opening the account: a jigsaw puzzle of their goal, a photo of their goal, or a pen. Those in the jigsaw puzzle group received a piece of the puzzle after each deposit.

In Bolivia, the researchers worked with a private bank, Ecofuturo, and sent text messages to clients of the Ecoaguinaldo program. This savings strategy aims to encourage people to deposit a certain amount of money every month; by the end of the year, they would have saved

the equivalent of one month's wage, the amount formal workers receive at the end of the year by law. When signing up for the program, clients determined how much they would save every month. If clients made all their deposits within the first ten months, they would be rewarded with a 6 percent interest rate (twice as high as they would receive otherwise) and a free life and accident insurance policy. Clients were randomly assigned to receive a text message. Some messages included reminders about the benefits, while others did not.

Using reminders proved useful not only in increasing savings, but also in increasing the likelihood that clients in Bolivia would meet their target amount (3 percent). Not only did the reminders have an effect, but the way in which the message was phrased mattered, as well. Reminders that highlighted the client's particular goal, such as school fees, were twice as effective as reminders that did not mention the goal. These findings are novel empirical evidence about the importance of reminders in household finance. This innovative use of modern technology to influence savings decisions proved effective, particularly given the low cost of cellular phone texting. The advantage of using text message reminders over mailings lies mainly in its cost advantage in terms of both money and labor. Comparing the results of the experiments in Bolivia and Peru, the researchers found that the bank receives a profit of about US\$0.20 per client with text messages, compared to a loss of US\$2.32 per client with mailings.

EXPANDING FINANCIAL LITERACY

Another tool to provide useful information to help clients make better financial decisions is information technologies. Hastings, Mitchell, and Chyn (2010) conducted a randomized experiment in Chile to determine whether providing workers with information on the variations in fees charged for pension funds made a difference in which fund workers finally chose.

In the experiment, the researchers used an on-site spreadsheet that computed the expected balance of each respondent's pension fund based on past returns and fund commissions, and each individual's wage, balance and age. The balances were computed for each pension fund, and shown to the interviewees in different ways. For one group, the returns were shown in comparison to the highest cost fund (highlighting the relative loss). For the second group, the returns were compared to the cheapest fund (highlighting the relative benefit).

The experiment found that people with lower levels of education, income, and financial literacy rely more on the advice of employers, friends, and coworkers than on fundamentals in choosing a fund. Further, the researchers found that such individuals are more responsive to the way the information is presented (information framing) when interpreting the relative benefits of different investment choices.

The Chilean experiment shows that financial literacy campaigns can be delivered with the help of information technology. However, the possibility of extrapolating these results to other contexts is limited. The use of information technology as a tool of financial education must take into account local market conditions and the likelihood that the ICT can be adequately adopted.

THE IMPORTANCE OF CONTENT

Researchers recognize that whereas ICT may provide a valuable tool to achieve financial inclusion and improve development outcomes in Latin America, they have become increasingly aware on the role of content that can be delivered using new and traditional ICT tools. In this context, recent research shows the role of soap operas as a potentially very useful mechanism that if paired with ICT tools can provide significant development results.

The key reasons of why soap operas work are summarized by La Ferrara (2016) and La Ferrara,

et al (2014). These and related work provide compelling evidence that creating characters, who are fully identifiable with viewers in terms of race, mannerisms, language, household characteristics, and the like can effectively help provide 'teaching moments' to viewers in a dramatized context. This tool has proven very effective in the case of financial inclusion (Chong & Valdivia, 2016) as well as in other relevant development outcomes frequently related with gender differences. In fact, a crucial objective of soap operas is to empower women through direct actions (e.g., savings on her name) and indirect actions (e.g., conversations with other women, and her partner) in order to reshape the current social construct. This approach is sometimes accompanied with the use of knowledgeable facilitators that conduct discussions with the viewers after each soap episode is shown as this further helps internalize the teaching moments as well as give them a forum to discuss.

The reason for the success of soap operas can be traced to three aspects, which summarize the theory of change. First, soaps are set up in easily recognizable locations and deal with the daily life of people, so that viewers can relate to the story. Second, soaps use colloquial language, identifiable setups, and often include an element of independence and social mobility that is highly appealing to viewers. Third, TV companies spare no expense in order to produce soaps of the highest technical and artistic quality, which makes them more attractive. The theory of change poses that soap operas play a central role for the functioning and process of articulating new behavioral patterns as it shows to give a sense of belonging and identification. It can have effects on values and attitudes, among other things, a reorientation of beliefs on the role of women in society toward greater autonomy and empowerment.

Soap operas in Latin America have shown promise in order to deal with difficult issues related to behavioral economics. There is recent academic evidence that shows that television and soap operas can have important social effects. Relevant work are Chong and La Ferrara (2009)

and La Ferrara, Chong, and Duryea (2012) who show that soap operas have an impact on divorce and fertility rates in Brazil. In addition, Chong and Yanez-Pagans (2015) provide evidence that television may impact negatively homicides in Brazil. Also, Dahl and DellaVigna (2009), focus on the short-run effects of movie violence on crime. In other disciplines, such as psychology Paluck (2009) estimates the effects on beliefs and norms of a radio soap opera featuring messages of intergroup tolerance in Rwanda. Furthermore, in Political Science Gentzkow and Shapiro (2008) have studied the effects of television on social as opposed to political behavior, in particular children's school performance and Olken (2009) has focused on adult participation in social activities and trust. Finally, in Public Health, Jensen and Oster (2009) estimate the impact that the entry of cable TV had on subjective measures of female autonomy, school enrollment and fertility.

The potential for scale of this type of innovations in the context of ICT is extremely high. Once the soap opera is produced, the marginal cost of showing it elsewhere is essentially zero, which means that the costs of massively broadcasting a soap opera as would be close zero. Furthermore with some caveats, it might be possible to scale it up to different Latin American countries, in particular, those that share similar cultural, racial, and historical traits. An example of this area commonality would be the South American Andes.

A LONG WAY TO GO

In spite of the enormous benefits associated with these new tools up to now, Latin America and the Caribbean have lagged well behind the rest of the developing world. There still is a long way to go before the poorest households in Latin America will be able to afford a computer and Internet service of their own. To date, Latin America and the Caribbean has been moving relatively slowly to exploit technology to foster financial inclusion.

Nonetheless, many pilot projects have taken off with the aim of achieving what Asian and African countries accomplished years ago—with the advantage of being able to take stock of the lessons learned.

ESCAPING POVERTY THROUGH TECHNOLOGY

Living in poverty is not only about not having enough money to purchase valuable goods and services; it is also about lacking access to the resources to break out of poverty and guarantee well-being. Access to information—through something as simple as a phone call—can enable the poor to use their own knowledge and strengths to escape poverty traps.

Information and communication technologies are a potentially effective weapon for fighting poverty as they can help people improve their incomes. The role of ICT in improving social and economic conditions in the world's poorest countries has been strongly advanced by the international community and many examples worldwide can be found, including in Latin America. Chong and de Mendoza (2011) documented a number of interventions in Latin American countries where the use of cyber-instruments contributed to earning opportunities for the population.

Furthermore, ICT have shown that they can be very effective in reducing discrimination in particular, towards the poor. Taking advantage of two randomized natural field experiments occurring in the context of the renewal of national identification cards in Bolivia, Chong and Yanez-Pagans (2016) provide evidence that computer technologies can be a very useful tool to significantly reduce discrimination by reducing discretion and by increasing implicit accountability. In fact, computers and related technologies have the potential to transform the way in which governments interact with citizens as well as on the manner in which services are delivered to the

public. They may be of important help in countless situations where the power and discretion of economic agents is unbalanced.

These researchers show that the introduction of computer technologies leads to impressive improvements in efficiency and productivity, and provide strong evidence that the introduction of these tools can lead to a drastic reduction in discrimination, something that is impressive given the significant differential service provision to individuals in their field experiment. Another important consequence of the introduction of computer technologies is that they also help reduce corruption in the public sector. In fact, given that discrimination and corruption appear to go hand in hand, this finding is of relevance as public service delivery in many countries is rife with corruption and as it is reasonable to believe that such link is not exclusive to their study. As these technologies continue to evolve, policy makers and regulators may increasingly adopt them not only as a tool to enhance government efficiency and transparency, but also as a tool to achieve more equitable societal outcomes

In general, there are compelling reasons to expect significant economic development from the adoption of ICT. One way in which these technologies can help bring about economic improvement is by reducing disparities and gaps in information (asymmetric and imperfect information) in markets. For example, individuals and firms can use ICT to research prices of products, look for jobs, or locate potential buyers of their products. This may be especially relevant for certain groups that are at a disadvantage with respect to others, either because they lack information or because their access to it is delayed or in a lower quality form. Low-cost access to useful information can help low-income families find economic and social opportunities that could benefit them. ICT can become a powerful tool to alleviate poverty, reducing uncertainty, promoting inclusion, and increasing income.

Asymmetric information and search costs are particularly detrimental in two specific markets:

agriculture and labor. In the agricultural sector, small producers usually sell their products knowing only prices in their local area. Cell phones give producers access to prices in other markets and open their eyes to the relative worth of their produce. Expanded mobile phone service, together with needed complementary public services (gathering, processing, and disseminating information in real time by agriculture and production ministries) give poor farmers the fodder they need to negotiate higher prices with intermediaries and wholesalers.

ICT have also proven their worth in the performance of labor markets. Job search activities require time and resources, and may lead workers to many dead ends. ICT can help reduce job search time and costs and therefore impact positively on unemployment rates.

FUTURE RESEARCH DIRECTIONS

Information and communication technologies are a potentially effective weapon for fighting poverty. They can help close information gaps, spread the knowledge available to a broader sector of the population and expand the opportunity frontier of the most vulnerable sectors. Armed with more and better information, the poor can be better equipped to act on their own behalf, boost their earning potential and use their own knowledge and abilities to lift themselves out of poverty. Furthermore, taking advantage on the anonymity of cyber-transactions, in the future these tools should focus on how they can help in reducing discrimination and corruption, something that the poor suffer disproportionately.

CONCLUSION

This chapter summarizes a number of specific cyber-interventions in the areas of finance, content, and poverty-reduction that have taken place in Latin America in recent years, which may lead to a

better understanding of the impact of interventions to know what works, what does not, and why. The common thread of all the existing cyber-behavior research in Latin America is that tools that take advantage of new information and communication technologies are not the panacea that policymakers want them to be, but with adequate content such tools may be very useful, as early evidence shows in the case of financial inclusion.

KEY TERMS AND DEFINITIONS

Development Economics: Branch of Economics that deals with aspects related to the development process in countries.

Financial Inclusion: Financial operations and tools that help increase availability and affordability to low-income segments of society.

Information and Communication Technologies: Tools that help manage information electronically. They may be catalogued as “traditional”, as in the case of television and radio and “modern” as in the case of smartphones.

Soap Operas: Serial drama that deals with the lives of characters in a dramatic and emotional manner.

The Growing Impact of ICT on Development in Africa

S

Sherif H. Kamel

The American University in Cairo, Egypt

INTRODUCTION

Information and communication technology for development (ICT4D) has been evolving for almost four decades realizing business and socioeconomic development and growth and capitalizing on channels for information acquisition and knowledge dissemination allowing the creation of an emerging global knowledge-based society with innovative means of communication that can help increase competitiveness for individuals, organizations and societies. ICT tools and applications could be used as an effective platform to minimize the digital divide and promote social inclusion. The transformation process enabled through ICT is affecting different aspects of the economy and is forcing governments to rethink the way they handle their socioeconomic challenges as they move forward in their development paths. This article addresses some of the initiatives in Africa to minimize the intra and inter digital divide, and join actively the global knowledge society by capitalizing on emerging technologies but more importantly by focusing on human capital as the most invaluable element in the technology ecosystem. Many African nations have invested heavily in building their ICT infrastructure with its different building blocks to help improve the readiness of their communities and smoothly integrate into the global digital world¹.

BACKGROUND

During the recent few decades, ICT tools and applications have transformed the way people live,

work, study, travel, and get entertained amongst other daily routines. The global ICT sector is currently a significant sector in its own right accounting for up to 7.5% of worldwide gross domestic product. ICT has not only changed the world, but it has also increased its potential (Figueres, 2003). In addition, with more challenges facing the world today, more opportunities are being created for ICT to have an effective role. On a different note, emerging and innovative ICT coupled with globalization and the role of societal norms, values and cultures are constantly affecting societies around the world. It is forcing organizations both private and public to rethink and reengineer the way they manage their operations and resources and face competition both locally and globally. Moreover, it is fair to claim that the processes of globalization are increasingly depending on ICT (Musa, 2006). This situation has generated new forms and structures of economic, business and social organizations that are no longer affected by geographic or time constraints but depend mainly on teleworking, telecommuting and overcoming barriers of time and distance which is emerging as the platform for business and socioeconomic development in the 21st century. The digital platform is increasingly becoming at the center stage of most businesses and industries. ICT has the potential, given proper infrastructure in place, trained skilled human resources and timely infrastructure, to improve the balance in economic and social progress, increase growth of the economy, boost the capacity to face societal challenges, enhance progress of democratic values and augment cultural creativity, traditions and identities (Kamel, 2009).

DOI: 10.4018/978-1-5225-2255-3.ch628

During the 1990s, there was an unprecedented link between the technological innovation process and the economic and social organizations. Moreover, as the links between economic development, productivity and the availability of information resources became invaluable, governments around the world started to invest heavily in building their national information infrastructure (Petrazzini & Harindranath, 1997). This led to major changes and transformations in the activities and relationships of individuals and organizations within the society, leading to the evolution of the information society, where the services provided by ICT represent a set of challenges and opportunities for the global society. However, it is important to note that, although access to ICT is a prerequisite to its use, individual differences in time and space as well as capabilities and choice may play a role on the use, value and application of ICT (Alampay et al, 2003).

In today's global environment, it is becoming easier within the context of business and socio-economic development and growth to identify and evaluate as well as compete across all sectors and industries using the wealth of information and knowledge that are disseminated through global information networks. The ICT infrastructure makes information more accessible with more benefits to the society (Shapiro & Varian, 1999), which puts more pressure on firms around the world to exploit all possible opportunities to leverage productivity and efficiency. Businesses are increasingly becoming more aware of the vitality of ICT to stay competitive, with other global implications to productivity, employment and profits to the extent that organizational operations are becoming unthinkable without the effective and efficient use of ICT, especially in a global society, where information travels across national boundaries (Branscomb, 1994). Moreover, societies, especially in the emerging world, are increasingly encouraging high-value innovative entrepreneurs in the ICT space who can seize the opportunities in the marketplace and offer solutions to various economic sectors (Strategy&, 2011). Therefore,

many developing nations including African nations have taken concrete measures in restructuring their ICT policies as part of their overall national strategies for development. This has resulted in having the number of mobile phones subscriptions growing twice as fast as that of the world during the period 2003-2008. Today, mobility, Internet dissemination and the growing diffusion of digital applications and tools are taking the African continent by storm, a leading example is M-Pesa Kenya's renowned mobile payment service, channeling 25% of the country's gross domestic product (GDP) showing how important mobile payment is becoming integral to economic transactions (Hossain, 2015).

The policies introduced included deregulation, encouraging private investment and foreign direct investment (FDI), and the use of tools such as public private partnerships. ICT is an opportunity for the developing world such as the African continent because it is a powerful tool for economic growth, social inclusion and poverty eradication, which can facilitate the integration of African nations into the emerging, digital global marketplace (Annan, 2003). Africa stands to gain a great deal from participating in the globally connected economy; however, it must first establish the necessary ICT infrastructure, and restructure government processed and avail suitable economic conditions to attract and maintain an effective position in the global economy (Ajayi, 2004; Akinola et al, 2012). One decade into the 21st century, the world is becoming smaller and the public is rapidly gaining access to emerging ICTs (Shapiro & Varian, 1999). The information society is becoming a global force and a fundamental element of change in the global society (Garito, 1996). In that respect, Africa is taking clear and robust steps to build its information, technology and communication infrastructure.

Investment in the ICT sector is perceived to have the ability to improve the lives of people with low income who have limited access to services such as healthcare and education (Qureshi, 2007). Moreover, ICT holds the promise of development

and growth by connecting people across the world irrespective of their background, location or cultural setting to more accurate and timely sources of information and knowledge (Ahmed, 2007a) and Africa should be at the center stage of that development given that still in the majority of African countries, less than 5% of the population use the Internet resulting in the fact that most African countries have an Internet penetration equal to or below 11% as compared to the global average of 23%. In recent years, that has resulted in having the percentage of growth of Internet and mobility usage among the highest in the world as the African nations attempt to close the digital divide with the rest of the world.

The Role of ICT in Development in Africa

Since the early years of the 21st century, there has been a high-level commitment from African leaders to bring about change in the way ICT is perceived as part of the Africa's infrastructure boom. The commitments were declared following the meetings of the World Summit on the Information Society (WSIS) in Geneva in 2003 and Tunis in 2005. Today, African leaders are more into the information age and they are more prepared than ever to initiate new ideas, formulate a vision, set the strategy and support it throughout the implementation phases. It is perceived that such a trend represents a unique opportunity for Africa's younger and growing generations to adapt and adopt new tools and techniques using state-of-the-art ICT.

The indicators demonstrate that the African ICT market is gradually rising with huge potentials to have positive implications on different economies. Given the size of the African continent, there is a huge demand for ICT that needs to be satisfied effectively in order to ensure effective participation of African nations in the global information society. In today's growing and fast changing marketplace, it is broadly believed that universal access to ICT through broadband and

access can contribute to economic development supported by governments, the private sector and the civil society. However, despite the developments in the ICT sector in Africa over the last few years, there are still a number of challenges to overcome before the continent is fully connected. The focus in the coming period should be mainly on the underprivileged communities and the rural areas. Moreover, ICT prices remain high and are unaffordable by the majority of the population who live in one of the poorest regions in the world.

While teledensity in Africa and especially in Sub-Saharan Africa is rather low, teledensity in rural areas is very limited. The gap between urban and rural areas in terms of telecommunication access is significant because the majority of the population is living in rural areas and underprivileged settings. It is estimated that in Sub-Saharan Africa nearly 66% of the population resided in rural areas. Within the context of Sub-Saharan Africa, there are around 400,000 localities, 99% are villages. Less than 3% of these have a fixed telephone line connection and less than 4% of the villages have access to Internet in public access centers. Accordingly, it is estimated that 55% of village population are not connected without access to fixed, mobile and/or data services, all resulting in negative competitive edge. Moreover, education, awareness and training are vital platforms for ICT to play an effective role in development. It is a two-way process. While education can help diffuse ICT, emerging technologies could also help spread awareness, education and knowledge. ICTs has the potential to increase access to education, improve teaching and learning and improve the efficiency of educational management and dissemination with the growing distance and blended learning environments. ICT could be the ideal platform for Africa to reach out to all remote locations and help develop a large and growing human capital expected to reach 2 billion people by 2050.

In the context of the developing world, the number of cellular M2M connections known as Internet of things (IoT) will reach a total of 128 million or 52 percent of the global connections

Table 1. M2M connections by region

Region	M2M % Total Connections (2013)	M2M CAGR (2010- 2013)	Connections CAGR (2010-2013)
Africa	1.0%	41.3%	15.0%
Asia	2.1%	55.0%	10.4%
Europe	5.1%	28.6%	2.4%
Latin America	2.1%	43.7%	7.8%
North America	9.3%	22.5%	3.6%
Oceania	5.1%	25.8%	5.5%
Global	2.8%	37.6%	8.8%

Source: GSMA, 2014

during 2015 and will rise to 575 million connections or 60 percent by 2020 (Reuters, 2014). Table 1 demonstrates the M2M connections by region.

African Information Society Initiative (AISI)

The information infrastructure is a strategic resource to be used by governments, corporations, and individuals to rationalize their decision-making process. The conference of ministers of the Economic Commission for Africa (ECA) in May 1995 adopted the Africa Information Society Initiative (AISI). The idea of AISI was to focus on policies, strategies, initiatives and projects that can help establish nation-based information societies that can help create the African information society. AISI is a common vision for Africa's quest to bridge the digital divide (UNECA, 2003a). One of the key components of AISI is the formulation of national eStrategies, also called National Information and Communication Infrastructure (NICI) plans with a view to achieve their development goals through the collaboration of key stakeholders from the government, private sector and the civil society (UNECA, 2004a; UNECA, 2004b). Three major development goals have been articulated by African leaders who represent the driving force behind the embarkation on ICT evolution across

the continent. They include improving the quality of life for every African, working on the integration of the economies of the different African nations and leveraging trade linkages with other regions outside Africa based on mutual development purposes and growth targets. The development of AISI enables African leaders, decision makers and planners to position Africa in the world's rapidly expanding global economic system and accelerate the pursuit of the continent's development goals. The emerging ICTs offer the potential to create jobs at much lower levels of capital investment and exploit Africa information resources without the need for corresponding financial wealth. However, the institutionalization of the process is an integral part of its success, sustainability and scalability.

ICT IN AFRICA

Emerging ICTs are perceived to be the possible driver for socioeconomic development in Africa. There is no doubt that African lives have greatly improved over the last decade with more promises for development and improvement in the coming decade. However, despite the success of the ICT penetration including mobiles and Internet over the last decade, there is limited proof of ICT contribution to development and growth. One of the reasons could be attributed to the lack of ICT market reforms that is essential to integrate ICT within the economic structure of nations, let alone the uneven balance and divide across different African regions. Both areas have seen concrete improvement over the last few years but more needs to be done moving forward.

Competition, although available and growing over the last few years, yet it is still limited and not as effective to introduce major changes and transformations. Therefore, there is additional work that needs to be done in terms of market regulations to ensure competitiveness, quality and service delivery. This is not to undermine the role of other stakeholders such as the private sector or the civil society but they all compliment and

are highly needed for ICT to have an effective role in development and growth. The regulatory environment will also address the issues of equality and inclusion within the information society. Additionally, a regulated and open environment is conducive to investments both local and through foreign channels such as foreign direct investment (FDI). There are different models in place whereas in the case of South Africa, they began using government investments for ICT infrastructure development, however, in the case of Uganda, the government entered into long-term agreements with the private sector to expand networks that are operating more efficiently within a competitive environment (Gillwald and Stork, 2008). There are a number of aspects that represents the ICT ecosystem and that need to be addressed to assess the evolution of ICT in Africa and that includes; (a) liberalization of telecommunication, (b) regulatory environment, (c) market segments, (d) revenues and investments, and (e) employment. These elements represent the building blocks based upon which ICT can effectively contribute to the continent's economic development.

In terms of ICT infrastructure, different means of communication are now widely available. In terms of statistics, Africa has three mobiles for every four people which matches the same penetration level as in India. Moreover, the bulk of mobile machine-to-machine (M2M) connections are in developing countries, including Africa. In Africa, there were 7 million mobile M2M connections in 2014 and the number can quadruple by 2020 whereas most Africans access the Internet from mobile services (Reuters, 2014). The proliferation of M2M started in the developed world but it is an area where the developing world has overtaken the developed world, and the African continent is taking the lead. The Internet of things initiatives and programs are mainly focusing on vehicle tracking, mobile payments (mPayments) and smart cities (Reuters, 2014). Today, across the African continent, capacities are being developed to connect everything to the Internet; moving forward is a world where every rural village,

urban city and community in Africa has wireless access (Presterio, 2014). Examples include South Africa, the continent's most advanced economy is the leader in rolling out M2M devices, one of the projects being smart meters for a power utility and Rwanda using SIM cards to connect point of sales (POS) terminals in remote locations enabling merchants to accept debit or credit card payments (Presterio, 2014).

Youth as the Opportunity

With a young population spread across the African continent, opportunities are being created around the clock. Youth including students are all over the continent increasingly using computers and tablets from home, schools, universities and Internet Cafés. Consequently, African statistics suggest that human development in sub-Saharan Africa has made huge leaps and there's an overall improvement in their skills and capacities (The Economist, 2013). For example, secondary school enrolment grew by 48% during the period 2000 and 2008. According to UNCTAD (2012); there has been an overall economic boom that in many ways made all the difference. Africa is the world's fastest growing continent. While over the last decade per capita income increased by around 30%, the previous 20 years had seen a low down in the continent's economy by 10% (The Economist, 2013). The opportunity is there for Africa to leap-frog and introduce, implement and institutionalize innovative technology applications.

Liberalization of Telecommunications

Historically, the role for government with respect to ICT in Africa has been that of an owner and operator of the incumbent public telecommunication operator (Touré, 2007). However, there has been transformation in the policy direction in recent years whereas governments in Africa are currently promoting competitiveness by establishing a sound policy framework and stable institutions.

Liberalization of the telecommunications sector has been a growing trend over the last couple of decades with a number of African governments committing to open up their domestic telecommunication market and introduce competition with over 50% of all Africa's fixed line markets are now subject to competition and nearly 50% have private-sector participation in their ownership structure. Consequently, the role of the private sector is increasing which effectively is healthier for the industry and can help create an environment that is more competitive, efficient and customer-oriented.

Regulatory Environment

UNECA has placed priority on building an information-rich continent through AISI with its framework that is geared towards developing NICI plans to complement liberalization and deregulation measures whereas nations are judged whether they are information rich or information poor (Ahmed, 2007b). Respectively, over 35 nations have been engaged in defining national policies and electronic strategies (eStrategies) as part of their socioeconomic development process. The impact of the liberalization process and the effectiveness of regulatory policies constitute a key indicator for measuring the effects of the information society in Africa. The rationale for the introduction of deregulatory measures in African telecommunication sectors relates to the economic principle of competition that could increase access and lead to the expansion of the ICT infrastructure. The measures were also geared towards stimulating incumbent national telecommunication entities to provide services in a more efficient and effective manner. It is important to note that in 1993, there was no country with a competitive market environment for telecommunication. Today, example nations that established organizations to regulate the sector include Morocco, which established the National Telecommunication Regulatory Agency in 1998 and Egypt, which established the National Telecommunication Regulatory Authority in 2003.

Market Segments

The market segments of ICT with an emphasis on telecommunications are divided into fixed lines, mobile lines, Internet penetration and broadband access. Most of the fixed telephone lines are concentrated in 6 of the 54 African economies. Algeria, Egypt, Morocco, Nigeria, South Africa and Tunisia account for almost 80% of all fixed lines in Africa. However, most these lines are located in major cities with some random diffusion in rural communities. Africa's fixed telephone line penetration was 3.1 per 100 inhabitants compared to a world average of 19.4 per 100 inhabitants, more than 6 times higher than the penetration rate of Africa. The continent has taken the lead in the shift from fixed to mobile telephony. Therefore, the mobile market in Africa is characterized for its impressive growth rates. North and Sub-Saharan Africa were able to add the largest number of new subscribers. Based on the above that indicates that mobile penetration and growth was more than fixed lines, Africa is the only continent where more revenues were generated from mobile services than from fixed line services showing the prospects of a full-fledged ICT infrastructure. It is important to note that low subscription prices, prepaid services and low recharging cards have contributed to the African mobile boom. Some African countries are approaching full mobile population coverage; Egypt reached that status in 2012 which was coupled with reduction in prices due to increasing competition.

In 2006, less than 3% of the world's Internet subscribers (10.7 million) were located in Africa, which means given the African population, this means that 1.3% of the inhabitants were subscribers to an Internet Service Provider (ISP). The estimated number of effective Internet users' stands at 4.8 users per 100 inhabitants. Affordability, lack of fixed line infrastructure and a low level of ICT literacy are the most striking reasons for the low levels of Internet use in Africa. However, it is important to note that African nations vary greatly in their Internet penetration rate ranging

from the penetration of 35.7 per 100 inhabitants in the Seychelles to 11 in South Africa and 8 in Egypt. The broadband access in Africa serves a limited number of inhabitants. However, with the decrease in prices of both voice and data the volume of bandwidth users is on the rise. The diffusion of bandwidth access is on the agenda of different African governments to be able to capitalize on the infrastructure of different electronic business applications. Moreover, bandwidth could be a determining factor in boosting investments and availing opportunities for offshore outsourcing (Touré, 2007). The deployment of universal broadband access could help create cost-effective and flexible standards for wireless technologies, extend coverage to geographically challenging locations and provide public service electronic applications. Africa's best performers when it comes to the state of the web are Tunisia, Egypt, Kenya and South Africa.

Employment and Job Creation

The telecommunications sector is a platform of income generation at the individual, organizational and governmental levels. The liberalization process and increasing competition helped expand the sector and made available more employment opportunities in the sector. The challenge of the sector is to avail regularly qualified human resources acquainted with the current and timely developments in telecommunications services and technologies. The drive of African leaders is based on a number of elements including the announcement of the G8 summit in 2000 that nations who will succeed in harnessing ICT potentials can look forward to leapfrogging conventional obstacles of infrastructure development whereas everyone should be able to access information and communication networks. The deployment of emerging ICT provides a unique opportunity to developing nations to capitalize on previous experiences and lessons learnt by various developed nations.

Challenges Create Opportunities

S

The formulation of the information society requires the collaboration of multiple stakeholders in the community including the roles of (a) government, (b) private sector, (c) civil society and (d) media. This can help transforming existing challenges into opportunities. The role of government should reflect an enabling environment to develop the national ICT infrastructure and to ensure that all sectors of the economy can benefit from it. Thus, each African government should assign a national entity to be responsible for the coordination between different stakeholders involved in the buildup of its NII. Moreover, African governments should promote the use of ICT to improve decision-making effectiveness. They should design, develop and implement national policies and plans adopting ICT within various sectors. The role of the private sector should be to stimulate growth and assume market leadership in developing national ICT infrastructure through investing in relevant areas and seizing new business opportunities that arise from the implementation of AISI. The role of the civil society should represent the catalyst coordinating with other stakeholders in establishing AII through identifying the needs of rural communities, contributing in human capacities development, reflecting public concerns and needs in terms of ICT and promoting the concerns of the workforce to employers and government. The role of the media is spreading awareness in Africa of the importance and benefits of the information revolution. Newspapers, radio, and television provide an easy, accessible, and cheap means of diffusing information to the end user.

CONCLUSION

The role of ICT for development is growing worldwide and associated policies and strategies are regularly amended to pave the way for an effective

ecosystem that can help ICT realize its targeted objectives. ICT is helping to avail the information society through ICT penetration across the community both urban and rural, which indicates the necessity to minimize the digital divide, work to socially, and economically include the underprivileged communities to become electronically ready. The information society will only be realized when there is a mature ICT infrastructure at a reasonable cost and with ICT penetration at both individual and organizational levels. The African Information Society is the least developed globally reflecting the most primitive information infrastructure indicating one of the least socioeconomically developed regions, despite the waves of change introduced over the last couple of decades in capitalizing on ICT and enabling ecosystem. The transition to an information-based society is so massive and comprehensive that, from a policy perspective, no nation can proceed on all fronts at the same time and it will all depend on the national priorities. African nations must develop their own infostructure with a view to a future connection to the global information infrastructure to bridge the gap with the developed world and to establish links for cooperation and exchange of experiences, skills, capacities and knowledge.

In that respect, ICT is causing an industrial and societal evolution based on information acquisition and knowledge dissemination and allowing the creation of an emerging information society with innovative means of communication that could help increase competitiveness for individuals, organizations and societies. To conclude, there is huge potential through the deployment of the Internet of things in developing economies during the next decade where the estimation reflects higher potential value in advanced economies because of higher value per use yet the developing world can benefit from around 40 percent increase of value generated. Another proof that emerging ICT platforms could effectively help African economies to grow. It will all depend on the business, industry and application and the readiness of both the technology

infrastructure and the timeliness, accuracy and access of the infostructure. Accordingly, the level of impact will vary dramatically. Examples for that include the health sector where healthcare spending in advanced economies is twice that in developing economies and in the retail sector, while higher adoption and values exist in advanced economies, there are large numbers of retail settings in developing markets. The potential is there and the opportunity could be created through the proper deployment of ICT, the key element is to have the clear set of objective and capitalize on the continent's most precious resource, people.

KEY TERMS AND DEFINITIONS

Africa: Referring to the African continent.

Developing Economy: Describing the economies of developing or emerging nations.

Digital Divide: Describing the gap between the haves and have nots in different countries when it comes to information and information technology access and usage.

Information Highway: Describing the digital platform enriched by repositories of information and knowledge that is universally accessible by the different stakeholders in society.

Information Society: Describing the type of society that is information-based that is supported by full-fledged information infrastructure (infostructure).

Internet of Things: The growing development of machine interconnectivity where every day more objects and machines have network connectivity, allowing them to send and receive data between each other.

IT for Socioeconomic Development: Describing the role of information and communication technology in the social and economic development process.

IT Transfer to Developing Nations: Describing the challenges and opportunities that emerge when transferring information and communication technology to developing and emerging nations.

Social Inclusion: Describing the efforts that are exerted to close the gap between the different social segments in the society with respect to social and economic aspects.

Manufacturing vs. Services and the Role of Information Technology

Indian Institute of Management Calcutta, India

INTRODUCTION

The role of technology in the context of structural changes of economies is often debated, mainly due to the mixed empirical evidence on the relationship between the technology adoption and productivity enhancement across countries. This has led to a policy debate regarding technology adoption by countries. In the context of developing countries, the debate is more on the appropriate set of technologies to be adopted rather than whether increased use of technology should be embraced. The endogenous growth theories (Romer, 1986; Rebelo, 1990) explain the role of technology as set of externalities which offsets the diminishing returns to capital. However, it is widely recognized that modern information technology (IT) is distinctly different from some of the past technological breakthroughs like industrial revolution. This difference comes from the unique feature of the use of IT which results in increased separation of the economics of information from the economics of things (Negroponte, 1995). In recent times, a number of studies have explored the role of IT in explaining the convergence of growth rate among countries (Rodrick, 2012; Greiner et al., 2016). However, there is a dearth of adequate studies on the impact of information technology revolution on the broader socio-economic context or structural transformation of a country. The present chapter aims to understand the same by analyzing the rather unique pattern of structural transformation of the Indian economy, which is characterized

by predominance of services sector mainly led by IT services.

The services sector, which now accounts for close to 60 percent of total GDP of India, has been playing an instrumental role in stimulating the growth of the country. A closer look at the GDP composition of India since independence reveals that while the share of agriculture declined and that of industry stagnated, services sector's share has exhibited an increasing trend to reach at 58 percent in 2009-10 from around 30 percent in 1950-51. The stagnating share of manufacturing and in contrast to that, rising share of services in GDP, is something noteworthy if one compares it with the structural change of countries comparable to India in terms GDP per capita. In most of these countries, the structural change has taken place in a common manner where an initially agrarian economy goes through the phase of industrialization, and then at a more advanced stage, services sector predominates. Many researchers concluded that India has leapfrogged the phase of industrialization and instead directly moved to a service-led growth phase. In the case of India, the stagnating share of manufacturing in national output as well as its reduced share in organized sector employment during the last two decades presages a phenomenon of de-industrialization (Chaudhuri, 2015). Does technology play a role in explaining the strange structural change of India? What is its impact in terms of employment generation and export performance? The chapter analyses some of these questions in detail. The analysis presented

in the chapter adds country-specific insights to the literature on the role of technology in economic development and structural change.

The remaining part of the chapter is organized as follows: the next section of this chapter presents a brief discussion of the existing literature on structural change and the role technology plays in it, followed by a description of the Indian experience of structural change in section 3. The later part of the section 3 also delineates the services sector in its present form in India. Section 4 and 5 provide an assessment of the consequences of services-led growth that India has experienced regarding employment and export performance, respectively. Finally section 6 concludes the chapter with policy implications that follows from the analysis and aims at making the technology services driven growth of India sustainable in the longer run.

BACKGROUND

In this section, first, we present a summarized description of existing scholarly works on structural changes of the economy. The second half of this section traces out the role of technology in the context of structural transformation.

Literature on Structural Change: Concepts and Theoretical Underpinning

The traditional literature of structural changes, describes industrialization as a main catalyst of technological innovation and productivity enhancement (Verdoorn, 1949; Kaldor, 1967). However, the same literature defines services as the outcome of “unproductive labour” (Smith, 1976), *i.e.*, products of labour that perishes the moment the labour is performed. However, a greater integration of national economies since the era liberalization has resulted in increasing importance of the services sector through international trade. In a similar fashion, we observe that

the literature on structural change and economic development during the 80’s and 90’s have started recognizing the potential role of services in the development process (Francois, 1990; Eswaran & Kotwal, 2002). There is no consensus in the literature regarding the relative efficiency of industry or services-led growth. However, when the sectoral composition of output of a country increasingly moves towards services at the expense of manufacturing before the country reaches a high level of per capita income, a phenomenon often termed as de-industrialisation (Rowthorn & Ramaswamy, 1999; Palma, 2005), it affects the employment generation and income distribution of the country.

A parallel stream of empirical literature probes into the relative importance of services versus manufacturing in the growth process across countries. (Eichengreen & Gupta, 2013) Many countries have experienced the wave of service-led growth twice in their growth process; once when they move from lower income to lower-middle income and again when they move from middle-income of upper-middle income. The first phase of services that had predominated the growth process while countries moved from lower-middle income to middle income were mainly low-end services. In the latter phase, services were mainly high-skilled and technology embedded. The second wave of services is more predominant in countries with strong democracy and locations closer to the financial hubs. One of the most important reasons underlying the services-sector boom in many countries is the “splintering effect”-the increased use of services by industry of these countries (Francois, 1990). This happens due to the change in production technology and subcontracting of services by many manufacturing firms, as they grow larger in size. According to some studies (Gordon & Gupta, 2005; Shingal, 2014) the boom of the services sector in India is attributed to demand-side factors, such as increased use of services in the manufacturing sector, and increase in domestic and foreign demand for services. From supply side factors, the reform and increased

flow of FDI boosted the services growth in India, which is most visibly prominent in the case of the telecom sector.

Role of Technology in the Context of Structural Change and Economic Growth

The role of technology in economic development is well recognized since the era of Schumpeter (1942), who, through his concept of creative destruction, first illustrated the role of invention in a capitalist economy. The literature on economic growth emphasizes the importance of technical progress in a more explicit manner since the early 90s (Aghion & Howitt, 1990). A parallel stream of literature focuses on the market failure that happens in the case of production of knowledge due to the infinite expansibility and non-rivalry (David, 1985). Quah (1999) explained how the IT, which is at the centre stage of the recent wave of technical innovation, differs from earlier technical breakthrough. To understand this, it is important to draw a distinction between those economic ideas which have economic value in their physical manifestation and those ideas which retain their value independent of the physical medium containing them. The unique feature of IT is that it reduces the distance between consumers and knowledge producers. Since IT products can be easily disseminated, even with the presence of copyright laws, it is not the supply but the demand side factors that determine the spread of such technologies in an economy. This is more so as the cost to consumers of using IT involves the associated cost of learning the technologies. An important policy conclusion that emerges from the nature of IT is that countries need to develop a sufficiently strong demand base for effective diffusion of IT in the economy. This can happen either through creating necessary skill and expertise among the working population or through specific government policies aimed at enhancing private use of new technologies.

In the context of developing countries, adoption of IT as a policy is often debated and remains a crucial public policy decision. The genesis of this debate can be traced back to the fact that even in some developed countries like the USA; the penetration of IT has not necessarily been productivity enhancing (Strassman 1997). In the context of developing countries as well, the empirical evidences on the relations between IT investment and productivity has thrown up mixed evidences (Kraemer & Dedrick 2001; Dedrick et al., 2013; Jin & Cho, 2015).

The conceptual model developed by Kraemer and Dedrick (2001) provides an excellent framework to understand the relation between IT investment and economic factors through a virtuous circle (Figure 1). The first half of the circle shows how economic factors determine the level of investment in IT. The other half of the circle shows how IT influences the national wealth, wage level and growth rate. The model concludes that IT enhances the national productivity through increasing the productivity of capital by complementing other investments.

MANUFACTURING VS. SERVICES- THE INDIAN EXPERIENCE

Following the theoretical foundation on the role of technology in economic development, this section deals with the structural change of the Indian economy since independence. The later part of this section describes the definitional concepts of the services sector in India.

Structural Change in Indian Services Sector

To understand fully the uniqueness of the structural change that India has experienced (Table 1), it is pertinent to compare the sectoral composition of India in Figure 2. In Figure 2, it is evident that services predominate India's composition of GDP.

Figure 1. IT investment and growth

Source: Kraemer & Dedrick, 2001

S

	1950-51	1960-61	1970-71	1980-81	1990-91	2000-01	2004-05	2012-13	Changes (1950-2010)
Agriculture	55.9	46.7	46.0	38.9	31.3	24.6	21.1	17.39	-41.3
Industry	14.3	19.0	20.3	24.5	27.6	26.6	27.2	17.64	13.8
Services	29.8	34.3	33.7	36.6	41.1	48.8	51.5	64.97	27.5

Figure 2. Share of services in GDP

Note: India's position is indicated by the red dot in the scatter plot. Data pertains to 2010

In India, the national accounts data classifies services sector into the following group of activities: wholesale and retail trade, hotel and restaurants, transport services, storage services, communication services, financial services, real estate, renting, business and other social, community and personal services (Ministry of Statistics and Programme Implementation (MoSPI), Government of India). A major limitation of carrying out in-depth empirical analysis in the area of services is the lack of detailed data on services in India. The services sector, in its present form in India, differs distinctly than the way it is defined in the traditional economics. Within the services sector, there exists wide heterogeneity regarding the nature of the industry (public versus private), capital intensity, employment generation capability, economies of scale, technological advancement and so on. The sectors such as telecommunication, banking, and insurance, IT are highly organized by nature with the proportion of organized sector being in the range of 80-90 percent in total output. On the other hand, there are sectors like wholesale and retail trade, real estate and renting and business services where this proportion is less than 20 percent.

The IT Industry in India

India has emerged as one of the major source for providing low cost technology solutions in the global market. The source of such comparative advantage is mainly attributed to the English speaking talent pool available in India. The software Industry in India began to take shape in its present form since the entry of Tata Consultancy Services (TCS) in 1970s in the industry. Following the success of TCS, many software companies were set up in subsequent years. The Indian software industry has a pyramid structure, with few large domestic firms accounting for more than 30 percent of total software export of the country and the smaller firms mainly providing low cost technology solutions to the domestic small and medium sized firms. While the initial trend in the

Indian software industry was “body shopping” *i.e.*, working onsite for US firms, the recent trend suggests a reversal of the same, with off-shoring activities increasing at a rapid pace. This recent trend also indicates that overtime:

- India’s IT industry has matured in terms of its competence
- The necessary infrastructure to work off-shore has been gradually building up in India (Bhatnagar, 2006).

At present, the software sector accounts for around 40 percent of India’s total services sector export and 9 percent of India’s GDP. The IT service industry in India grew at a rate of 10.3 percent in recent years in terms of export. The sector plays a strategic important role not only in shaping India’s growth story in recent years by growing at around 8.5 percent per annum, but also by employing 3.5 million people in the domestic market (National Association of Software and Services Companies (NASSCOM), 2016).

MANUFACTURING VS. SERVICES-FROM THE EMPLOYMENT PERSPECTIVE

India’s workforce is still predominantly agrarian in nature (Table 2). Moreover, the proportion of employment absorbed by both manufacturing and services are quite at a low level if compared with the other low-income countries. As pointed out by Kochhar *et al.* (2006), the lower employment generation capability of Indian manufacturing can be attributed to three important reasons:

1. The state-led heavy industrial policy adopted by India thriving capital intensive sectors in manufacturing
2. The rigid labour laws
3. The education policy of India favoring tertiary education

Figure 3 clearly indicates that the state-led heavy industrialisation policy adopted by India after independence has made the manufacturing sector of India more capital intensive and skill-based as compared with any other comparable countries. The rigid labour laws of India further add to the limited employment generation capability of Indian industry. For an example, an amendment to the Industrial Disputes Act (1947) in 1976 made it mandatory to the firms with more than or equals to 300 workers to seek the permission of the relevant government for any downsizing activity. Apart from the factors mentioned above, the fact that India's investment in education is highly skewed towards tertiary education also explains why the endowment that India possesses today is different from any other low-income countries (Kochhar et al. 2006). This relatively skill-intensive workforce also explains the rise in the service sector of India.

Banga (2005) pointed out three reasons behind the slower employment generation of services sector in India:

- Sectors that have high employment generation potential are growing more slowly than skill-intensive sectors.
- The faster growing services sectors are also sectors with higher productivity.
- Trade in services is accelerating the growth of sectors which are highly skill-intensive in nature.

Before examining the relative importance of these three points in explaining the slower growth of employment in India's services sector, a closer look at the break up of services sector according to their employment capacity would be pertinent. From Figure 4, it emerges that wholesale and retail trade is the largest employment generator within the services industry, followed by transport, and hotels and restaurants, all these together accounting for more than 60 percent of total employment in services. The five-yearly moving average growth rate of different sub-sectors of services (Figure 5) reveal that trade, hotel, transport, and communica-

Figure 3. Value-added share by skill-intensity

Source: Kochhar et al., 2006

Figure 4. Employment within services-sub sectors

Figure 5. Sectoral growth rates

tion has exhibited higher growth rate as compared with the average growth rate of services shown by the shaded line. Hence, it is difficult to argue that sub-sectors with greater employment generation

capability within services have slowed down in recent years. In the context of productivity growth in Indian services industry, there are very few studies that empirically examine the productivity

growth of sub-sectors with services. One such study by McKinsey and Co (2001) concludes that sectors like telecom, banking, construction, and retail distribution exhibit high productivity level. This could explain the limited role played by these sectors in employment generation.

Lower employment capacity of services sector is another reason behind falling employment elasticity of the sector. This is mostly visible in case of wholesale and retail trade, the segment accounting for the largest share of employment within services (Table 2).

Another explanation of the slower growth of employment in services is the skill-intensive nature of these sectors. However, as discussed earlier, services are a highly heterogeneous set of activities and there are large variations regarding skill requirement within sub-sectors. Also, the urban informal services sector in India is low-skill based and supposedly to have higher employment generation capability compared with the high skill intensive sectors like IT and financial services. The extent to which education acts as barriers to entry in services sectors could be partly captured by the proportion of professional, managerial and technical workers in the total workforce.

MANUFACTURING VS. SERVICES-EXPORT OPPORTUNITIES OF INDIA

During the last two decades, India outperformed all other countries in terms of services exports.

India runs a sizable trade deficit in merchandise trade balance as opposed to a trade surplus in services. While India's share in the world merchandise trade export stood at around 1.52 percent in 2009, India's penetration in the world market in case of service is more than double, standing at 3.6 percent during the same time. The revealed comparative advantage (RCA) index of India for merchandise *vis-à-vis* services clearly indicates the fact that India's comparative advantage in services exports is significantly higher than that of manufacturing. Figure 6, 7, 8 and 9 clearly depict the facts mentioned above.

An in-depth analysis of export data for different sub-sectors of manufacturing indicates that the deteriorating trade balance in merchandise exports in case of India is primarily attributable to chemicals other than pharmaceuticals, aircraft, specialized industrial machinery, telecommunication equipment and parts, computers and general industrial machinery. According to Lall (1999) and Chaudhuri (2013), the decelerating merchandise exports of India is attributable to the structural weakness embedded in the composition of manufacturing goods in India's export basket, which is predominated by technologically primitive products, and thus not able to reap the benefit of sustained growth in world merchandise trade. The same becomes visible on comparing the proportion of high-technology products in total manufacturing exports of India with that of some newly industrialized countries (Table 3).

Table 2. Employment elasticity in different sub-sectors in services

	1989-90 to 1993-94	1993-94 to 1999-2000	1999-2000 to 2004-05	2004-05 to 2009-10
Construction	1.00	1.00	1.09	0.48
Trade	0.63	0.55	0.35	-0.07
Transport, storage and communication	0.49	0.69	0.48	0.08
Banking and insurance	0.92	0.73	1.24	0.27
Community, social and personal services	0.50	0.07	-0.10	-0.14
Services	0.41	0.15	0.45	-0.01

Figure 6. Average growth rate of services exports: 2000-2010

Figure 7. Trade balance (USD Million)

According to the estimates provided by Chaudhuri (2013), services such as telecommunication, IT, air transportation has grown phenomenally, thus creating huge demand for computer hardware, telecom equipment, and aircrafts. Due to the inadequate expansion of these sectors, most of the

need are met by way of importing, thus worsening the merchandise trade balance of India during last one decade (Chaudhuri, 2013).

India's RCA in services exports is mainly explained by the large pool of labour force, with varied skill-sets and English-speaking ability. Ac-

cording to Chanda (2010), there has been a shift in the export composition of services of India from traditional services such as transport and travel towards emerging services like software, accountancy, engineering, and health in recent years. The analysis presented in the same paper indicates that the RCA index has risen sharply for services like software, consulting management, financial and communication. Other regulatory barriers to trade in services have significantly been reduced as a part of the economic reforms

introduced in 90's, accelerating FDI flow and growth of services in India.

FUTURE RESEARCH DIRECTIONS

Based on the analysis of earlier sections, it becomes evident that technology played an important role in shaping India's structural transformation. The slower growth of manufacturing in India is due to lower technology adoption of the sector.

Figure 9. Revealed comparative advantage of India

Also, emergence of IT-BPO industry in India is mainly driven by demographic factors rather than advancement of indigenous technology. In this context, the following policy perspectives aim at spreading the use of technology to make the growth story of India more broad-based and sustainable in long run.

Need to Invent Technology to Boost the Industrial Growth of India

Despite the presence of a thriving services sector, there are few instances where India has been able to invent indigenous technology to boost its manufacturing sector. One of the crucial reasons for the poor performance of Indian manufacturing is identified as low technology adoption (Planning Commission, 2011). At this backdrop, there is a need to create the necessary institutional set up required for invention, diffusion and adoption of technology in the India's industrial sector, a major part of which remains informal in nature even decades after the reform took place (Raj & Sen, 2016). This also implies that India needs technology not only to improve its export performance, but to enhance the inter-sectoral linkage as well. Hence, technology which works at grass roots level is the need for the hour in the case of India

to facilitate its growth story. A slew of recent initiatives taken by the Government in recent times including Digital India, Start Up India and Udyog Aadhar are steps to the right direction.

Need to Spread Use of Technology in Education

The sustainability of the services-led growth of India crucially depends on availability of English-speaking efficient workforce. Based on the survey conducted by Kuruvilla and Ranganathan (2008), it is found that there are a number of human resource related issues challenging India's sustainability in this field in the longer term. Also, there exists a vast urban informal services sector which presently plays a critical role in absorbing low-skilled migrants from rural parts of the country. In the setup, India needs to improve the spread and quality of its vocational education which is crucial in improving productivity in urban informal services segment. The importance of Tele-learning and Tele-training remains significant in the context of India. The National Education Policy of India 2016 specifically highlights the use of information and communication technology (ICT) to spread education at grassroots level in India.

CONCLUSION

Due to the heterogeneity in terms of skill-intensiveness within the service sector, the nature of employment also varies a lot. Though many organizations employ highly skilled salaried personnel, there exists no stable employment or social safety network for people working in the urban informal services sector. In this context, the setting up Unique Identification Authority of India (UIDAI) as a separate entity by the Government of India is an important and significant step which uses information technology to enhance inclusion of marginalized population in the growth process. In order to improve the employment condition in the urban informal sector, specific government policy measures are required for the workers' health and education perspective. One such example is setting up of the community service centers first conceived by the National E-governance Plan (NeGP) of Government of India in 2006. This, along with a broad-based policy of technology adoption would help India sustain its growth story in medium to long term.

KEY TERMS AND DEFINITIONS

De-Industrialization: The term is used to describe declining industrial profit and labour displacement due to increased innovation and use of technology in industry.

Revealed Comparative Advantage Index: It is based on the notion of comparative advantage pioneered by Ricardo in the theory of international trade. The index is calculated as: $RCA = (E_{ij} / E_{it}) / (E_{nj} / E_{nt})$ where: E: Exports, I: Country index N: Set of countries J: Commodity index t: Set of commodities.

Services: The tertiary sector of the economy (also known as the service sector or the service industry) is one of the three economic sectors, the others being the secondary sector (approximately

the same as manufacturing) and the primary sector (agriculture, fishing, and extraction such as mining). It mainly comprises of the “intangible goods” like tourism, healthcare, hospital and other public services.

Splintering Effect: Splintering occurs when a part of the activities in manufacturing sector is outsourced to the services sector. For example, painting a car is often outsourced from the automobile industry to a services firm. This is also known as “fragmentation” of activities in the economy.

Verdoorn's Law: Named After Petrus Johannes Verdoorn (1949), the law states that in the long run productivity generally grows proportionally to the square root of output. As a result, in the presence of increasing returns, faster growth in output results in faster growth in productivity.

New Faces of Digital Divide and How to Bridge It

Viktor Freiman

Univesité de Moncton, Canada

INTRODUCTION

The objective of our chapter is to explore, through the lenses of digital divide, what are challenges to alleviating socio-economic and intellectual limitations for prosperity of each individual. Will new technologies and access to them really help to develop citizens who are able to contribute in creative and democratic ways to society? In order to answer this question, we extend our work presented in Martinovic and Freiman (2013) to:

- Identify factors to consider in designing flexible, innovative, and inclusive programs for all citizens to enable them to successfully function in the era of the Internet, new media, and computer technologies.
- Analyze how digital divide problematizes one's chances to be involved in the knowledge economy.
- Investigate ways in which digital divide may be circumvented.

In the past 15 years or so, Information and Communication Technologies (ICT; e.g., personal computers, cell phones, Internet) have become pervasive in developed countries, such as Canada and the USA. These tools can be used for both in-school and out-of-school activities, and are particularly suitable for connecting individuals and communities globally (Beetham, McGill,

& Littlejohn, 2009). However, many countries could not provide to their citizens the same level of access to digital technology, which, in its turns risks to deprive them of opportunities to develop abilities necessary for a meaningful use of digital technology and computer networks, including the Internet to gather, manage, and evaluate information, to create documents in multiple media forms, and to communicate at distance, are all aspects of digital literacy, as delineated in various policy documents (e.g., California Emerging Technology Fund, 2008). In fact, digital literacy has become almost a prerequisite for creativity, innovation, and entrepreneurship, all the irreplaceable attributes of the 21st century citizen (Beetham, McGill, & Littlejohn, 2009). However, although it is recognized that technology may positively affect both social and cognitive development of every citizen, it may also create or maintain economic divide across students, teachers, and schools (AERA, 2013), as well as between social groups or societies, even in the most developed countries..

Our effort to examine these tensions that in our opinion go beyond the usual issues of “have’s” and “have not’s” arises from the literature review study (Freiman, Martinovic, & Karadag 2011) we conducted upon request of the Ontario Ministry of Children and Youth Services (MCYS, 2012). Authors of numerous sources we reviewed, including position papers, government-ordered reports, as well as research data, relate digital divide to

DOI: 10.4018/978-1-5225-2255-3.ch630

several aspects of ICT, such as machine vintage, connectivity, online skills, autonomy and freedom of access, technical support, and interest in using the technology (Hawkins & Oblinger, 2006; Oblinger, 2008).

BACKGROUND

By introducing the concept in early 2000s, an OECD report (OECD, 2001) identifies two types of digital divide, the first one, based on the opportunity to access digital tools, including the Internet, and the second one, related to the ability to use those tools. For example, Norris (2001) argues that digital divide appears as result of uneven growth of the Internet resources, their multi-dimensional character, as well as transitory nature of the process associated to this growth. Also, in early 2000s, Attewell (2001) and Swain and Pearson (2001) identify the discrepancies in access to technology as the first digital divide, while differences in the effective use of ICT belong to the second digital divide; thus users with only basic access to technology can be disadvantaged, being technologically illiterate because of their limited opportunity to use digital resources. This view is shared by Dance (2003), who compares the cyberspace netizenry to citizenship in the ancient Athenian democracy that excluded women, slaves, and those with foreign origins. In like fashion, today's cyber netizenry ends up forming cyber-elite (i.e., an information-rich, digerati, and virtual class). Dance (2003) further points to some older reports that demonstrated that the digital divide in the USA was growing and had a deeper and more far-reaching impact than before. In this way, the digital divide resembles the economic divide: The (information) rich get richer, while the (information) poor get poorer.

In order to better grasp a potential impact of digital divide on individual, groups and societies, we should start with a brief clarification of terminology. First, as pointed out by Chen and Wellman (2003), the digital divide has multiple

faces and should be termed “digital divides” (p.3). In order to be addressed, various aspects need to be considered: physical access, financial access, cognitive access, content access, and political access (Wilson & Wilson, 2000). Second, the term “digital divide” has both technological and social resonances. Next, DiMaggio and Hargittai (2001) identify five dimensions of digital inequality: equipment, autonomy of use (location of access), skill, social support, and purposes for using the Internet, while Cuneo (2002) lists twelve perspectives on the digital divide. These include: demographics (e.g., computer per person ratio), age, gender, geography (i.e., where one lives-infrastructure), disposition to ICT (e.g., fear, lack of confidence), learning (e.g., traditional vs. on-line), disabilities, and economic, social, labor-related, cultural, and political factors. The author further declares that “in some ways education is at the heart of the Internet and the Digital Divide because of the importance to society of transmitting information and knowledge” (p. 25). This view is shared by Negroponte whose quotation “... The digital divide is a learning divide - digital is the means through which children learn learning” can be found in many reports of the launch of the “\$100 laptop” project (see, for example, Twist, 2005, para. 36-37). Moreover, van Dijk (2006) resumes his review of studies on digital divide conducted in 2000-2005 by arguing that “in terms of physical access the divide seems to be closing in the most developed countries; concerning digital skills and the use of applications the divide persists or widens” (p. 221).

In this optics, an analysis of digital divide conducted by Dewan and Riggins (2005) pointed at the importance of taking into consideration three levels of digital divide, namely individual, organizational and global ones. According to them, at the individual level, variations in access and/or the ability to use technology can be analysed among different segments of a social system, as well as policies that address these divides. At the organizational level, several factors (size, geographical location, industry, and ownership

status) need to be considered when looking at adoption and the ability to exploit technology in organizations. Finally, at the global level, differences between countries can exist in terms of the access and the use of technology related to their wealth, education levels, infrastructure, and other socio-economic factors.

MAIN FOCUS OF THE ARTICLE

Issues, Controversies, Problems

A cross-country analysis using data on computer use and Internet use determinants in 161 countries in the world, conducted by Chinn and Fairlie (2004) found that economic variables (income per capita, years of schooling, illiteracy), demographic variables (youth and aged dependency ratios, urbanization rate), infrastructure indicators (telephone density, electricity consumption), telecommunication regulatory quality are largely responsible for disparities between countries. The authors put income differentials, telephone density and regulatory quality on the top of their list of factors explaining the global digital divide (*idem.*)

There seem also to be an overall agreement that some groups may face additional vulnerabilities and opportunities in “the digital Era.” Several studies provide us with examples of facts that digital technologies do not necessarily promote fairness and equality between individuals, groups, and societies. According to Willms and Corbett (2003), having access to both a computer and the Internet at home is strongly positively correlated with socio-economic status (i.e., the higher the parents’ socio-economic status, the more likely that students have access) and also with gender (i.e., girls are less likely to have access than boys). Boyd (2007) argued that Facebook members, the so-called “hegemonic teens,” represented primarily the middle and upper middle class, whereas MySpace members, the so-called “subaltern teens,” came from mixed-class or lower class backgrounds (p. 41). The researchers also found

that children from immigrant families appeared to have a better chance of having a home computer and Internet access than children from mainstream families with higher socio-economic status. Immigrant families tended to invest more in their children’s education to ensure that they possessed highly sought computer skills.

Also, it is notable that the Internet is still used by minority groups and indigenous peoples primarily for community building and for access to alternative viewpoints that may not have found a place in the mainstream media (Budka, Bell, & Fiser, 2009). Indigenous Internet practices, for example, appeared to distinguish between inward and outward activities (Landzelius, 2006), that is, between how indigenous people present themselves to the outside world and the activities that serve for identity-finding and for strengthening intercommunity relations. Landzelius concluded that the Internet, as a connecting technology, helps some boundaries to dissolve, but intensifies others. While, according to Landzelius (2002), the Internet may help indigenous youth to find their cultural identity through connections with similar youth on the Internet, this may exacerbate their exclusion from the mainstream societies in which they reside.

At the global level, saying that the debate about the first digital divide related to the access issue is closed seem to be too optimistic, as mentioned by Steyaert and Gould (2009) who cite www.internetworldstats.com (December 2008) that only approximately 1.5 billion people, or 22 per cent of the world’s population of 6.6 billion have access to the Internet. Moreover, the UNDP (2007) report, to which refer Steyaert and Gould (2009), reveals that industrialized countries, with only 15 per cent of the world’s population, are home to 88 per cent of all Internet users. Other facts given by the authors extend a quest for investigation and discussion, namely that London, UK, appears to still have more Internet domains than the whole of Africa. Already in early 2000s, Finland alone had more Internet users than the whole of Latin America without mentioning that ‘the telephone

directory for Manhattan is bigger than that of the African continent, and 50 per cent of the world's population has never made or received a telephone call' (UNDP, 2007, p.743).

The results of a study conducted by Mardikyan et al. (2015) show that, global digital divide has a significant difference in almost every categorical variable which is studied. There are significant differences between continents, and income levels in terms of ICT Development Index. Similarly, there is a significant difference between developed and developing countries and between OECD member and not member countries in terms of this index (p. 9). At the same time Pick and Sarkar (2015) draw attention to the fact that besides differences between nations, generally well documented in the literature, that can be significant discrepancies within one country, on the state, province, prefecture levels which are less known.

In terms of progresses made by different countries in different parts of the worlds, a recent study conducted by Skaletsky (2013) reveals different patterns in terms of improving the access to technology and its meaningful use. It shows, for instance, important progress made by the Eastern European countries whereas in African and Latin American countries issues seem to remain unsolved (idem.). Even in developed countries, like the U.S., while some gaps (e.g., gender-related) are diminished, others (e.g., ethnicity, education level, and age) seem to remain and even widen, which puts a question mark on 'the promise of information technology to benefit traditionally disadvantaged demographic groups and provide a more level playing field for academic and economic marketplace achievement' (Losh, 2010, p. 218).

Moreover, if one recognizes the existence of digital divide, and this, at different levels, its impact on people's life and society, as whole must be questioned, according to Bourdeau de Fontenay and Beltran (2008) who argue, at the same time that 'where digital inequality amplifies inequality, the digital divide needs to be evaluated on its own' (p. 4). While research evidence

points at the access to technology as one of major indicators of digital inclusion, simply providing an access is not helpful without the commitment to a concomitant development of higher levels of critical thinking. Even if we recognize a well-established fact that countries with increased ICT penetration rates can provide more access to ICTs than before, and as a result, could decrease adolescents' reliance on school ICT, according to Zhong (2011), increased ICT penetration rate does not enhance adolescents' self-evaluation of their digital skills. In other words, as mentioned by van Deursen and van Dijk (2011), the "original digital divide of physical Internet access has evolved into a divide that includes differences in skills to use the Internet" (p.893).

At the same time, Schrock and Boyd (2008) have raised the concern that digital literacy phenomena themselves are in a constant state of flux and thus are moving targets. Understanding what online/mobile environments are available for learning and skill development, as well as how these environments can enhance purposeful collaboration among the young, may affect, for example, programs dealing with such matters as anti-cyberbullying, reduction of poverty, social inclusion of recent immigrants or Aboriginal populations, and promotion of digital literacy among girls. Significance of their study is in opening up a discussion beyond an understanding that the first digital divide relating to access to technological infrastructure and hardware has been almost resolved, at least in Canada. Worldwide, example of the second divide can be easily extended. For example, Minghetti and Buhalis (2010) found that a number of causes, such as lack of knowledge, trust, literacy, language skills, and content availability of credit card and low bandwidth can explain digital divide in the tourism industry.

Further, Chen and Liu (2013) point at the rural-urban gap, as well as imbalanced allocation of educational resources as one of the major factors of digital divide. Also, the authors show limited access to digital teaching materials and online learning in disadvantaged areas due to license

restrictions, copyright issues and the high cost of information sources as example of how this factor affects small (and often in rural and remote areas) communities. For example, Rekhari (2009) shows that in Australia, twice as many as non-Indigenous people those from Indigenous communities do not have yet Internet connection.

In some way, wireless networks and small affordable computers based on the open source software (such as a “\$100 laptop” initiative, MIT project) promise to make computers not only potentially but actually ubiquitous, can help in reducing costs. However, it is incumbent upon educators not only to know about these developments but also how to adapt to new societal needs for citizens who must become capable problem solvers and lateral thinkers; persistent and determined learners; open-minded and progressive strategists; and, confident users of technology (Martinovic & Magliaro, 2007).

Therefore, we emphasize that addressing the second digital divide must happen through improving digital literacy competencies among all citizens. This is why educational issues should be brought at the upfront of societal debates that would extend meaningful use of technologies above formal ones found in academic routines of educational institutions but very important in everyday life of learners (Karsenti & Collin, 2013). In the same way, Zhong (2011) reports findings showing no significant interaction between what is done with ICT access at home and ICT access in school. Also, there are studies expressing concerns about a ‘failure of traditional academic literacies to engage marginalized populations’ (Pirbhai-Illich, Turner, & Austin, 2009).

On the other side, Wiseman and Anderson (2012) found that “ICT in instructional practice has not gone much past the entry level of use in the Gulf Cooperation Council and around the world...This indicates that even where schools and classrooms are well-equipped for computer resources, educational systems cannot ‘buy’ learning and knowledge with resources” (p.614).

Thus, different groups may become disadvantaged in terms of usage of digital technologies, especially regarding the digital literacy. For example, recent study of Kuo, Tseng, Lin and Tang (2013) reports that of the 771 million adults who are still digitally illiterate, the majority are women, which is, according to them the third most important issue that women face globally. With a growth of social networks worldwide, some authors point at reluctance to some aspects of their use by elderly citizens in situations of learning, self-expression, and building, maintenance and sharing of identity through digital technology, as they may perceive those situations as posing a threat to their identity (Martin, 2009). This can be an indicator of another group that may need special attention and help to become fully integrated in a digital world.

SOLUTIONS AND RECOMMENDATIONS

Based on the literature, it is plausible to conclude that while some divides disappear or get minimized, the others appear. Based on Canadian context Cuneo (2003) lists twelve perspectives on digital divide, arguing that it is necessary to deal with issues of disposition and skill that teachers have with ICT, as well as labor conditions under which teachers work. Professional development opportunities that range across all education layers need to be provided, including reasonable evaluation of increased workload in presence of ICT. Karsenti & Collin (2013) express the same view: “Il revient aux institutions éducatives d’assurer la formation des apprenants aux usages éducatifs des technologies (...)” (p.205). For Pirbhai-Illich, Turner and Austin (2009), to build future selves for students include succeeding in school and overcoming their current life circumstances, which means that the researchers “acknowledge the need for instruction that develops both academic and new literacies, exemplified in the multimodal media production where they can envision new

possibilities (p.159). Zhong (2011) adds that “both the school and the family can construct supportive social environment for adolescents” because “when an individual child has trouble using ICTs teachers, family members and peer students can offer help” (p.745).

In fact, different countries appear to handle digital divide with different levels of priority. For instance, as mentioned by Ferro et al. (2008) the theme of digital divide has moved higher on the list of priorities in Europe, as a key pillar of the Strategic Plan i2010, while the latest initiative of the US administration for expanding broadband access in schools nationwide (The White House, 2013), opens more opportunities for inclusive education of new generations of students. At the same time, many authors stress an urgent need to elaborate government’s technology policy in narrowing different types of digital divide, such as mentioned above Rural–Urban Knowledge Divide in higher education (Chen & Liu, 2013) for instance, to authorize teachers to provide online learning courses for pedagogical purposes, and to offer the right for rural student and residents to access online learning resources and knowledge with the financial help of the government. In a similar way, the ICT use can be effective in empowering young Aboriginal people (Singleton, Rola-Rubzen, Muir, Muir & McGregor, 2009). For Rekhari (2009) for instance, “indigenous people recognise the role that ICTs can play as a tool in self-determination” (p.179), and an online space can provide opportunities for “sparked an exchange of culture, creativity and experience between non-Indigenous and Indigenous young people” (p.178)

Kuo, Tseng, Lin, and Tang (2013), on their own account, take interest in female learners and show that with “sufficient social support, female learners build up their computer self-efficacy, persevere with ICT learning, and promote their subjective well-being” (p.214). As for Martin (2009), he focuses on seniors and asserts that “the perception of seniors’ relevant and effective digital action is important in challenging the “gen-

eration gap” (p.12). At their turn, Wiseman and Anderson (2012) consider that addressing a “need to provide training and professional development in ICT-based instruction” can help developing educational systems, such as Gulf Cooperation Council’s ones’ (p.615).

In case where disparities exist between different social groups within one country, like in the South Africa, where an English dominated ICT field gives advantages to the English-speaking learners in relation to using ICT, it is suggested by Gudmundsdottir (2010) to place increased focus on adapting ICT to the local curriculum, local needs and the linguistic environment of the users as a recommendation meaningful for other countries with similar issues.

Besides education, other factors should be addressed, once we talk about a digital divide convergence. For example, a model developed by Kyriakidou, Michalakelis, and Spicopoulos (2011) allows for predicting that by 2018, European countries will come closer, in terms of broadband diffusion.

Overall, despite a widespread optimistic assessment of potential of education to bridge digital divide, concerns expressed by Sciadas (2001) more than a decade ago about lack of understanding barriers to access and use of new technologies still remain actual field of research and practice. In fact, as pointed by Sinclair and Bramley (2011), “digital inclusion will only be achieved if the social rather than technological barriers inhibiting digital engagement are addressed” (p.1).

Through synergistic partnership between teachers, administrators, researchers, and students, the school system will be able to move closer to achieving the goal of purposeful and pedagogically meaningful use of ICT within daily classroom pedagogy, alleviating digital divide and inequity.

FUTURE RESEARCH DIRECTIONS

As mentioned by Billon, Lera-Lopez and Marco (2010), investigating ICT adoption and access

is necessary, but studies must now focus on the acquisition of skills needed for a more productive use of technologies, such as the Internet. It could be expressed by a nation level study of ICT use in education systems (Wiseman & Anderson, 2012) joined with a rigorous conception of digital practices and expert knowledge of learning design. For instance, it will be important that the researches centre on the development of teachers' pedagogy and ICT use (Wiseman & Anderson, 2012).

In addition, Kuo, Tseng, Lin, and Tang (2013) consider that "It is important to identify the reasons for (...) illiteracy and the methods required to foster and encourage female ICT learning" (p.217). Also as pointed out by Salman and Rahim (2012) the literacy, knowledge and technology motivation of the Internet of the users need to be further study in order to achieve a digital inclusion. Asiedu (2012) suggests that one direction could be finding innovative ways of incorporating attractive features of dominant communication mediums (the radio in his study) into ICTs. Rekhar (2009) proposes research on a more inclusive future for Indigenous and non-Indigenous people.

CONCLUSION

Consequently, we have come to the conclusion that new technologies and access to them really help to develop citizens who are able to contribute in creative and democratic ways to society. Yet, a number of conditions must be carried out. First, we have to include all the aspects of digital divide: physical, financial cognitive, content and political accesses; second we have to consider the technological and social resonances of digital technologies because, these latter do not necessarily promote fairness and equality. At last and over all, we have to take in consideration that providing an access to digital divide is not helpful without a concomitant development of critical thinking.

KEY TERMS AND DEFINITIONS

“\$100 Laptop” Initiative: MIT project related to developing a cheap, yet powerful enough laptop suitable to outlive the harshest environmental conditions and provide connectivity and learning to children most affected by the digital divide and poor social conditions.

Digital Divide: Difference in opportunities that individuals, groups, and societies have in adequately accessing and using digital technologies.

Digital Inclusion: Providing equal opportunities to all to live successfully in the Digital Era.

Digital Literacy: Ability to use digital technologies appropriately for learning, working, and functioning in a modern society.

Global Digital Divide: Global disparities related to access to computing and information resources, mainly between developed and developing countries which results in less opportunities derived from such access.

Information and Communication Technologies: ICTs include personal computers, laptops, PDAs, cell phones, computer networks and the Internet.

Rural–Urban Gap: Usually as a consequence of a lacking interface and poor broadband conditions, some rural and remote areas may be digitally disadvantaged.

The Potential Role of the Software Industry in Supporting Economic Development:

S

Sherif H. Kamel

The American University in Cairo, Egypt

INTRODUCTION

Emerging information technologies provide a solid and promising platform to support economic development. In that respect, the information and communication technology (ICT) sector has been one of Egypt's strongest economic sectors with increasing prospects for job creation, productivity, scalability, impact and growth (Mahmoud, 2011). One of the subsets of ICT, the software industry, is gradually becoming more visible, stronger and mature in terms of output and impact both locally and beyond. Software is virtually embedded in every single aspect of our daily life with growing impact on individuals, organizations and society (Schroeder, 2013). In the information age, everything needs a software, one way or another. The software development industry is increasingly becoming global and consequently, there is a growing number of software companies that are providing their services overseas through outsourcing and offshoring. Software is arguably the best entry platform for developing nations, like Egypt, into the global ICT production complex (Heeks, 1998). The exposure to products and services from different global markets and the accompanying growing competition have effectively led to improved software products delivered coupled with an increasing pool of ICT professionals and developers who are well-educated, multilingual, and technology-savvy and at the same time interested to take the local software industry to the next level.

During the last two decades, pro-business government policies and regulations have helped grow the software industry and have encouraged a number of multinationals to invest in Egypt including, but not limited to, the likes of IBM, Intel, Cisco, Google, Microsoft, EMC, Valeo and Oracle. They have all invested substantially in setting-up facilities and growing their operations, and more importantly deciding to offer their services out of their Egypt-based operations. Moreover, more local companies and startups in the software development space have started their operations over the last decade trying to capture a segment of the regional and global market opportunities. This article assesses the developments in the software industry in Egypt and the potential role it can play as a contributor to economic development through the establishment of an export-oriented outsourcing software industry capitalizing on one of Egypt's primary resources, human capital.

BACKGROUND

The ICT sector in Egypt has been steadily growing since the late 1980s. During the period 2011-2012 given the political developments that took place in the country there was an apparent slowdown in all economic aspects, including ICT. However, in 2013, the minister of ICT expected the sector to go back to its double-digits growth by the end of 2014 to match the growth that was taking place during the period leading to the fiscal year 2009-

2010. Moreover, it would come at an ideal time as a solid platform and a strong and effective support mechanism to the overall economic revival of Egypt. For the long term, projections indicate that by 2017-18 annual growth rate will reach 20% and will account for 6% of the gross domestic product (GDP) and the sector will help create 500,000 jobs (Helmy, 2013). These projections naturally change on a regular basis. However, judging from the potential and trends in the marketplace, there is enough evidence that the software industry is probably on course to meet these set objectives.

The ICT industry includes different aspects such as people, hardware, and telecommunications. However, software represents an enabling platform linking all different aspects (Tayia & Wahba, 2001) and a possible area of growth and comparative advantage for Egypt. The key determining factor remains is human capital. Within the ICT industry, the innovation ratio in software development has been lower than that of hardware and telecommunications systems (Bozzetti, 1999) which led a number of developing nations such as India to position the development of a software industry as a strategic option (Tayia & Wahba, 2001). This was supported by the fact that the cost of establishing the software industry in developing nations is relatively low (El-Deeb, 2012). Therefore, since the late 1990s, Egypt has decided to follow that path and different stakeholders have collaborated to help establish a software industry capable to gradually become one of the primary support vehicles to economic development while emphasizing the export-oriented elements in the mix to help improve the nation's current massive and growing trade deficit. The importance of software is that it emerged as the digital brainpower of ICT becoming a platform for economic growth and as the driving force among different economic sectors (Nordhaus, 2000). In 2015, Egypt ranked 100 by the global innovation index among 141 countries worldwide indicating improvement compared to a few years back and promising to offer new developments and advancements in a

variety of sectors including the software industry (WIPO, 2015).

The developing world started to use and produce software in the 1950s and 1960s (Heeks, 1998). During the 1960s computing was introduced to Egypt. At that time, its primary use and applications were limited to the government and the public sector with some modest use within the private sector. During the 1980s, the diffusion of computing gained momentum and was widespread following the global personal computer (PC) evolution. Although computing started in Egypt over 50 years ago, it was only in 1985 that the active role played by the government caused a change in the way ICT was perceived as a vehicle for socioeconomic development and as a tool to improve the decision making process (Rizk & Kamel, 2013; Kamel, 1999). With the establishment of a ministry for communications and information technology (MCIT) in 1999, Egypt's information society initiative (EISI) was launched in 2001 to provide a broad perspective on the strategic plan for ICT diffusion in Egypt (Kamel, 2005).

The general perception indicates that the way developing nations will manage the computer driven processes of change will undoubtedly influence whether its socioeconomic development goals will be promptly, effectively and efficiently achieved. This has also been explicitly mentioned in the Millennium Development Goals (MDGs) and articulated in both meetings of the World Summit on the Information Society (WSIS) in 2003 and 2005. According to Kamel (2010) this could be achieved through "focusing on stimulating the growth of export-oriented activities as opposed to local infrastructure development where attention will be directed towards innovation as a primary driver for future growth." It is all about developing a vision, providing the right enabling environment and be driven by clear objectives supported by the required resources financially and more importantly human capital.

Since 2005, there has been various efforts and steps taken to position Egypt as an alternative

location for investment in intellectual capital as well as offering software development, business process outsourcing, business process offshoring and call center services. This has led Egypt to invest in accelerating its high-tech infrastructure by developing technology parks with over 130 multinational company in the areas of ICT, software development, outsourcing and call centers. This included the establishment of the Smart Village in Giza in 2001, followed by a similar smaller version a few years later in the suburb of Maadi in Cairo and most recently the Tahrir Alley Technology Park (TATP) was established at the Greek Campus of the American University in Cairo as a hub for tech startups. This is an area that can grow fast and that already saw the establishment of multiple startups in the space of IT. Moreover, the growing interest and operations of some of the global players in the call centers and outsourcing space in Egypt has been very encouraging. Sample of these companies includes Sykes, Stream, Convergence and Sutherland and more (Mahmoud, 2011). The number of companies, their capacities and services offered have been gradually increasing over the last decade, creating employment opportunities both directly and indirectly and supporting a variety of economic industries and sectors.

As one of the world's leading outsourcing destinations, Egypt is expanding its operation aiming to increase earnings and contributing to the economic growth as well as emphasizing higher-value services and niche segments (Oxford Business Group, 2012). Through the ICT sector, Egypt operates virtually everything from inbound call centers to multiple offshore functions and services. Sample multinationals operating in Egypt include the Oracle global product support center established in 2005, Stream Global Services, Sutherland Global Services and a finance and accounting base for IBM (Oxford Business Group, 2012). The call center industry is growing fast with companies like Xceed pioneering in that field in Egypt with branches in Morocco offering their services in nine different languages (www.xceedcc.com). Given the demographics of

the population in Egypt where the overwhelming majority (58%) are under the age of 25, the outsourcing industry provides youth with thousands of job opportunities on an annual basis, contributing effectively to the 800 thousand jobs that need to be created annually (www.idsc.gov.eg).

Table 1 demonstrates the current demographics of the ICT sector in Egypt. It is clear that there was an exponential increase in all indicators that was realized post Egypt's uprising in January 2011. This was caused by an overwhelming engagement of the nation's youth in learning, communicating, and exchanging ideas and starting-up IT companies and the creation of an environment that aims to promote freedom of expression, inclusion, entrepreneurial activities and more engagement of different constituencies in policy making and development at large. It is important to note that despite the economic challenges that Egypt is facing, one of the few sectors that managed to float and maintain its steady operation and in some ways grow is the ICT sector which reflects many positive signs of its potentials and how it can effectively contribute to the future of Egypt. The overall theme that has been gradually but forcefully disseminating across the community is three-folds including entrepreneurship, innovation and responsible business.

In 2007, MCIT formulated a strategic three-year plan for the ICT sector with a primary mandate to surpass 1 billion US dollars in terms of IT export revenues by 2010, that target has actually been realized with an additional 10% reaching 1.1 billion US dollars by 2011 largely due to the growth rate in the sector which had reached 14.9% in 2009 and the growing number of multinationals in the ICT sector that had expanded their businesses and/or outsourced their operations to companies in Egypt (Abdelazim, 2010). According to the Information Technology Industry Development Agency (ITIDA), there are plans that revenues should hit 10 billion US dollars by 2025. Undoubtedly, this could have been realized based on the growth rates that were realized in the years 2009 and 2010. Both the government and the

Table 1. Electronic readiness in Egypt

Indicators	Dec 2006	Dec 2008	Dec 2011	Dec 2012	Dec 2013	Dec 2014	Dec 2015	July 2016
Internet Subscribers	6 million	11.4 million	29.8 million	22.6 million	25.7 million	28.3 million	29.8 million	30.8 million
ADSL Subscribers	206,150	593,042	1.65 million	2.24 million	2.49 million	3.12 million	3.03 million	3.79 million

business sector relentlessly continue to position Egypt as one of the key outsourcing destinations enticing the likes of Motorola, Orange Business Services, Videotron, HSBC and many others to either establish or expand their outsourcing and offshoring operations in Egypt.

Egypt's current plan given the relative saturation in the telecommunications infrastructure, is to focus on digital Arabic-language content, value-added services, digital services and software development (Kamel, 2010). In addition, with more than 800,000 university graduates annually, MCIT works with local companies and multinationals in the ICT sector to ensure that the required balance of skills and capacities are embedded in the curricula or through specialized educational programs to bridge the gap between the skills of Egyptian youth and the required competencies by the job market.

Since the establishment of Egypt's information society initiative in 2001 and based on models of public-private partnerships (PPP), there has been

a growing and effective role being played by the private sector through a win-win formula that is applied on a variety of ICT projects that related to a number of aspects included but not limited to software incubation and development (Kamel & Ahmed, 2006). In terms of the software industry, knowledge acquisition and transfer are key where 95% of the software development business is intangible capital (Grant, 2000; Hoch et al., 2000). Since the late 1980s, Egypt has been playing a leading role in software publishing in the Middle East and 80% of its software exports are regularly going to countries in the Gulf region and mainly Saudi Arabia (Fergany, 2002).

An Agile Software Industry with an Economic Impact

With a population of about 90 million people, Egypt is the most populous country in the Middle East North Africa (MENA) region with over 25% (over 23 million) of its population enrolled in

education programs, over 20 million represent its private sector workforce and around 7.1 million work for the government (www.idsc.gov.eg). The government of Egypt is more determined than ever to complete its national infrastructure and keep pace with the IT evolution worldwide. With the growing size of the global software market, Egypt has promising potentials to compete in the middle market segment of companies because it can not compete with the likes of India on the basis of prices. It can only compete based on the relatively low price of labor compared with the higher level of value added, business vision, and innovation (Rizk, 2002). Recently, focus was mainly on mobile applications for different sectors including but not limited to banking, health, education, trade, and industry as well as an increasing variety of services. The platform is a cutting-edge startup environment driven by passionate and technology-savvy youth opportunity. In addition, a growing number of software companies owned by Egyptian diasporas located in Europe and the U.S. are relying mainly on their software development activities on a pool of talented software developers located in Egypt.

The software industry in Egypt is growing and is attracting considerable investment from the private sector, in addition to the government incentives supporting the sector. Nevertheless, it is still in an early development stage covering four main market segments (Kamel, 2004) including software tools, packaged applications, customizations of existing applications and Arabization. The need for Arabic-language software remains highly needed especially with the size of the population in the region and its steady annual growth, which could represent a niche software companies (El-Kassas, 2005). The industry is labor intensive and faces opportunities to expand in global markets. There are various local, regional and global motives for Egypt to heavily invest in building an export-oriented software industry. Today, there are over 750 companies working in the software industry with over 18,000 professionals employed.

In 1999, Egypt supplied 70% of the demand for software from the Gulf region, primarily represented by the United Arab Emirates and Saudi Arabia (Kamel and Hussein, 1999). Multimedia-related products such as cultural, educational, entertainment and religious CDs are the leading products exported to the region. The majority of Egyptian software companies have established branches in United Arab Emirates, Saudi Arabia, Kuwait, Bahrain and Oman. Some are primarily working on outsourcing their services to the UK and the United States as well as other European and Far East countries. The government has a comprehensive program to support the software industry that includes a series of incentives such as formulating legislations offering five-year tax holiday for all software companies and 10-year tax holiday for the software companies establishing their operations in the established industrial zones. More is being done in that space especially supporting tech-startups and promoting entrepreneurship and innovation in the software development ecosystem.

The software industry is divided into four categories including (a) software tools, (b) packaged applications, (c) tailored applications and multimedia applications and (d) Arabization of applications. Software development companies range in size from 1 to 5 staff members' startups to relatively mature firms with around 50 to 150 employees. The majority of firms are located in and around the major cities including Cairo, Giza and Alexandria; where more than 60% of the population resides. However, recently, attracting talent has been growing across Egypt's different provinces with some of the promising ideas coming from Upper Egypt and attracting venture capital and angel investors to finance them. Diversity and pooling talents from across Egypt has been one of the elements of the recent developments in the software industry. Opportunities are also created in the various technology parks established to provide support in positioning Egypt as a global destination for outsourcing and offshoring, a

Table 2. Projections of IT exports by 2010

ICT Industry Element	Target Revenue (Million US\$)	CAGR	% of Total
Software and IT Services	280	27%	34%
Arab Content Management	200	46%	12%
Technical Support Centers	200	27%	24%
Contact Center Markets	115	50%	6%
R&D Engineering Design	100	38%	8%
Business Process Outsourcing Services	75	72%	2%
IT Product Exports (Emerging Markets)	45	25%	6%
IT Localization	40	22%	6%
Knowledge Process Outsourcing Services	30	43%	2%
Total	1,085		100%

Source: A. T. Kearney, 2005

position Egypt achieved in 2011 by being ranked 4th according to A. T. Kearney (2011). Table 2 demonstrates the projections of IT exports for 2010 as projected by A. T. Kearney.

Since 2005, the ICT sector, through public-private partnership programs have been focusing more on encouraging innovation and developments in ICT applications and in the development of the software industry with an emphasis on exports. Therefore, the government established four centers of excellence in data mining and computer modeling; wireless technologies, mobile and electronic services and electronic design. Egypt's dream is to become a leading software exporter in the MENA region with a global outreach which is relatively realistic considering the boom in the software industry in Egypt and the potentials in the regional marketplace with an increasing need for Arabization in a market with a population of 350 people and growing. This is also boosted by a growing trends in electronic commerce and the digital economy at large with all the associated opportunities created.

The competitive advantages of Egypt's domestic software production environment have attracted numerous international producers to subcontract programming of tailored applications. The industry was further boosted in 2004 with the establishment of ITIDA, a governmental entity established through Law 15, and aiming at paving the way for the diffusion of electronic business services and supporting an export-oriented IT sector. This was coupled with a number of strong attributes that placed Egypt as a potential center for offshore IT services such as a) favorable technical staff and infrastructure costs, b) language capabilities, c) improving infrastructure, d) pro-business governmental reforms, e) strong government support for the IT sector and f) a strategic geographic location. However, among the multiple challenges facing software development is the issue of intellectual property rights as the most critical barrier for the future growth of the information technology infrastructure in general (El-Kassas, 2005). Enforcement of existing laws should take place given the multimillion dollar losses incurred in the regional markets in general, Egypt included, on an annual basis. Further efforts need to be deployed at the institutional and implementation levels. The provision of laws without the proper follow-up and addressing the evolving problems has not met the expected levels yet (Corea, 2003).

An Industry-Based SWOT Analysis

The software industry in Egypt is better demonstrated through a SWOT analysis in order to understand where it stands and where it is heading with an overview of its strengths and weaknesses and an identification of the opportunities available and the threats faced as shown in Table 3.

FUTURE RESEARCH QUESTIONS

Based on the assessment of the software industry in Egypt, an action plan needs to be formulated in

Table 3. SWOT analysis of the software industry in Egypt

Strengths	Weaknesses
■ Young population that is tech savvy. ■ Educated graduates interested in ICT, entrepreneurship and startups. ■ Computer science majors in all public and private universities. ■ Training programs in IT applications. ■ Growing technical skills in ICT. ■ Low and competitive labor costs. ■ Good command of English for dealing with overseas customers (other languages include French, German and Spanish). ■ Same time zone advantage with Europe and provides a second-shift for the United States (outsourcing and offshoring services). ■ Government facilitating procedures and logistics related to the software industry.	■ Lack of sufficient expertise in any technology. ■ Need to improve expertise to compete in global markets. ■ Software companies spend 6+ months to prepare graduates for the marketplace (skills gap). ■ Lack of project management, communication marketing and managing startup skills. ■ Limited local demand for software. ■ Effective role of government is still limited. ■ Infrastructure level and cost is high compared to the capacities of different stakeholders. ■ Lack of government enforcement of regulations regarding piracy and intellectual property rights violations. ■ Perception that software has little intrinsic value among commercial and government customers.
Opportunities	Threats
■ Creation of more software business incubators-technology parks such as the smart village model. ■ Provision of internships and scholarships from software vendors both local and multinationals. ■ Promotion role played by software associations to activate the role of software development companies. ■ Changes in taxation and the introduction of new intellectual property laws. ■ Growing local, regional and global markets for diversified software development.	■ Intellectual copyright violations. ■ Piracy rates are relatively high. ■ Lack of market research in domestic and overseas markets that Egyptian companies could target. ■ Lack of financial support to the industry. ■ Limited outreach programs to penetrate the global software marketplace. ■ Other competing countries are rapidly developing their stature in the software industry space.

an attempt to capitalize on the opportunities available and overcome the challenges in the market. Such plan needs to be dynamic and iterative in a way to allow introducing changes based on market transformations and constant assessment of needs. The plan can assist Egypt in improving its software industry performance and cope with the global trends and drivers especially in the domain of outsourcing and offshoring. The plan could include issues such as identifying and penetrating global markets to realize growth; investing in people to leverage the technical skills and capacities in the industry; introducing business-incubator programs to link industry to educational institutions and the government; improving the infrastructure to ensure that firms have the vehicle to operate their business; and, increasing the government support role to demonstrate the value of the software development industry to Egypt's economic development (Kamel, 2003).

The plan should attempt to answer some of the research questions that could be addressed

as the software industry develops and grows and that includes whether developing nations can earn billions from software exports? Whether developing nations are relatively less expensive locations in terms of infrastructure, infostructure and humanware for software development? Whether software piracy is negatively affecting the production of software in developing nations? Whether the research and development efforts support the organization of a growing and an agile software industry? If the human capital in emerging economies have the ability to compete on a global scale? In addition to many more questions that address the different elements that relate to the proper development, sustainability and scalability of the software industry.

CONCLUSION

Egypt has an excellent opportunity to establish a relatively small but effective software industry.

The efforts and support enabled by the government, industry, financial institutions and the educational sector will ultimately determine the level of development and success of the industry hopefully making it an effective contributor to Egypt's economic development. The initial required resources to become a leading player in the regional market and possibly establish a global reputation as a software development hub are available in terms of technical capacities, skills and educational infrastructure. However, there are a number of issues that need to be addressed including the unbalanced distribution of qualified human resources, the lack of business non-technical experiences and skills needed to compete in global markets and the need for more support from different financial institutions primarily for startups. In addition, there needs to be a long-term strategy aimed at reconfiguring the educational ecosystem to cater for the growing needs of information and knowledge-based societies and that should be coupled with programs and incentives to minimize the possible industry-related brain drain.

Based on the development of the software industry globally and the potential for the software industry in Egypt; there is a number of issues that need to be restructured to benefit from opportunities available both in Egypt and other countries in the region. These issues relate to enabling better linkages and coordination between industry and academia; formulating an overall assessment mechanism; improving the education and learning ecosystem to deliver the capacities required by local and global markets; improving the industry salary scale to relatively match other regional and global markets in order to minimize the implications of brain-drain situations; setting-up a regulatory authority for the software industry, and excelling globally through offshore and outsource business development and contact centers.

KEY TERMS AND DEFINITIONS

Arabization: The transformation of software applications into the Arabic language in terms of usage as well as interface to be able to cater for a community that stands in 2013 at around 370 million people.

Building Blocks: Reflects all the critical success factors of the information and communication technology industry and that include: hardware, software, human resources “humanware”, networking and information “infostructure”.

Business Process Outsourcing: Means the use of outsourcing mechanisms locally or offshore for the design and/or development of software applications.

Information Technology Outsourcing: Reflects the outsourcing of computer or Internet related work, such as programming to other individuals or companies.

Information Technology Startups: They are the small and medium-sized enterprises and startups that are focused on information technology applications and services.

Diffusion of Information Technology: It reflects the spreading of information technology concepts among the society of implementation whether that could be within an organization or within the community at large.

Government-Private Sector Partnership:

The teaming of different entities in the government and the private sector to realize a change and a transformation in the development of information technology at large and in the software industry in specific.

Incubator Programs: A form of collaboration between industry, corporations, the business community and the educational sector through the availability of “space” that is used to formulate solutions that meet market needs and consequently help create employment opportunities especially among the youth.

Informatics Projects: The projects that involve in any way possible the use, design, delivery, implementation and management of information technology irrespective of the elements involved including software, hardware, telecommunications and others.

Information Technology Industry: The accumulation of all elements of information technology design, delivery and management coupled with support services and other human capital elements.

Smart Village: The concept reflects a model technology park represented by a landscape comprising office space designed for different development and service-oriented offerings of information and communication technology companies; thereby giving each the benefit of economies of scale; usually located outside the city.

Software Industry: Focuses on the needs of the software development industry in terms of infrastructure, know-how, capacities, research and development and lifelong learning.

Tailored-Applications: Applications based on industry or organizational needs to complement the off-shelf software applications available in the marketplace.

S

Socio–Economic Processes, User Generated Content, and Media Pluralism

Androniki Kavoura

Technological Educational Institute of Athens, Greece

INTRODUCTION

Media pluralism that is associated with the presentation of different points of view and ideas in media content, consists of a recurrent issue of discussion because it is in close relation with the socio-economic, technological and political environment within which media operate. Major developments take place with the worldwide economic instability that exists but also with the advancement of new technologies and social media that enhance online communication. International organizations such as the European Union have recently created a monitoring tool about media pluralism for European member states to utilize. It is at members' states own discretion the extent to which they will enforce media pluralism that at times relates to socio-economic and technological processes within their boundaries. In other geographic frameworks, such as Latin America, political issues influence media diversity and limit the possibility of different voices to be heard.

This paper aims (a) to present media pluralism's components and (b) to describe the reciprocal role between media pluralism's dimensions and communication technologies, socio-economic and political processes that take place. These processes are based on the technological advancements of new media platforms such as online video platforms and streaming services as media types for online media content. In doing so, this chapter adds to the literature by illustrating the role of the abovementioned processes on media pluralism. Media pluralism is under continuous negotiation. Current real-world scenarios are discussed that

aim to illustrate the dimensions of media pluralism and are of value to professionals in the media.

Which is the case when information and communication technologies allow for new online content material to be uploaded and become viral? Does this safeguard democracy in media and ensure that all voices are heard? The cases that are presented in this chapter as far as media content is concerned, are mainly taken from electronic media, television and press. Alternative approaches are presented as recommendations in need to take place for media pluralism and how online communication and new technologies can guarantee such expression of multiple points of view. These are renegotiated issues that the agents involved with the production and distribution of media content, -policymakers, media managers, marketers, firms-, can contribute so that media pluralism prevails. The creation and distribution of media content that presents different points of view, -minorities, underrepresented groups-, is affected by the rapid development and substantial impact of technological and communication changes. The chapter argues that diversity in media content may be influenced in periods of economic recession that a country may face. In addition, political and social reasons may influence the advertising budgets spent that in turn have an effect on media pluralism.

The next sections briefly describe media pluralism's dimensions and the concept of concentration of media ownership in relation to the technological advancements, user generated content created online as alternative media content, socio-cultural and economic processes in order to provide the framework and current trends. The use of exam-

ples aims to illustrate the way advertising media planning may be also influenced due to limited diversity in media content. Presentation of cases from countries where socio-economic and political processes and technological advancements may influence the media content diversity allows for recommendations to take place with the provision of alternative ways that enforce media pluralism. Recommendations to agents involved in the implementation of media pluralism are provided and suggestions for further research are given.

The researcher searched well-known databases which were Science Direct, Scopus, Emerald, Eric, E-List for available literature and search engines such as Google Scholar and Science Direct. The specific keywords under examination were the ones which were associated with media pluralism, media diversity, social media, user generated content and pluralism in the current socio economic processes.

BACKGROUND OVERVIEW: MEDIA PLURALISM

The definition of the concepts involved in the creation of the argumentation of this chapter entails media pluralism that consists of the umbrella that embraces aspects of media diversity. Media pluralism refers to more than one, in fact, numerous points of view and a variety in media content so that many people and groups can be represented (Valcke, Sukosd, & Picard, 2015).

Media pluralism is associated with and influenced by the presence of a wide framework of ownership and merger control requirements, a range of content in programming via different media types and genres, the existence of a variety of sources that contribute to the media content, viewpoint diversity and freedom of expression, independence of public service broadcasting in the content and program services provided, representation of local and regional interests, cultural expressions, limited or non-existence of clientelism relations

between media and political actors (K.U. Leuven et al., 2009a). The abovementioned dimensions when followed and implemented by agents, aim to provide access to information sources to all people. Pluralism though, continues to be the object of political contestation because it is influenced by the environment within which it operates, where continuous processes take place and the countries' specificities need to be taken into consideration from time to time (Leandros, 2010; Brogi & Dobrev, 2014). Towards this end, media pluralism needs to be holistically approached.

Valcke et al. (2015) categorize media pluralism as 'external' and 'internal' where the former has to do with the multiplicity of media outlets, the existence of many media owners so that media concentration does not take place and multiplicity in the operation of media in regard to the way expression of opinions and different points of view takes place; the latter, 'internal' pluralism is associated with the activities implemented by a broadcaster or a publisher to make every possible effort to produce a variety of and different media content material.

Within the European Union, a study was commissioned titled Media Pluralism Monitor (MPM) to develop a monitoring tool for providing member states with the possibility of assessing media pluralism and justifying whether or not pluralism exists in countries according to specific dimensions: media ownership, cultural, political and geographic diversity, regulatory framework, media types and genres (K.U. Leuven et al., 2009a). In 2013, the European Parliament awarded another grant to continue the implementation of MPM so that member states can be included (Brogi & Dobrev, 2014). At the time of writing this chapter, an ongoing research takes place on MPM. Although measures and a regulatory framework exists, each member state may act independently on the enforcement of specific legislation for plurality at national level. Thus, advocates of plurality and diversity argue that there is freedom of will that may safeguard media pluralism. Habermas

(1989) argued for the public sphere indicating the principled pluralism that guarantees freedom of public opinion, freedom of speech, freedom of press and the absence of constraints in expression. This takes place in environments where democratic institutions prevail. Nonetheless, in reality, different agents, -advertisers, media producers, politicians and others, may make use of the creation and distribution of media content based on the connections they have with media (McNair, 2011), thus, influencing the end result.

At the other side of the coin, competition and the free market may prevail. This, though, may be harmful for pluralism because it does not allow for differentiation in media content and thus, leads to reduction in diversity content (K.U.Leuven, 2009b). Competition is associated with the free will of all to participate in a free market provided they have the means to participate so that everyone can play with the rules of the market. Issues of agents' ownership, market, competition, exclusion, marginalization may take place and we may speak of an uncontrolled free market systems (Gantzias, 2014; Vamvakas, 2006). In this way, unfair competition is created, the media with the most powerful force and greater financial standing dominate while there are television stations that have the power and can influence public opinion even if web TV broadcasts. In press, a similar situation may take place even if the advancements of new technologies and digital communication allow for an easier dissemination of communication messages.

The element of commercialization generates communication associated with the dominance of advertising and the disparity in communicative resources (Vamvakas, 2006; Masouras, 2015). Media content uses the results of surveys of audience measurement and other marketing and communication tools that influence the viability of these programs based on the number of people that follow the program. Whatever cannot be sold, is not broadcasted and everything depends on such results.

CONCENTRATION OF MEDIA OWNERSHIP

Concentration of different media ownership under one owner is a dimension that may influence media pluralism. It usually takes place after mergers and acquisitions take place and brings forth the issue of representativeness and freedom of expression in media content. Lack of different points of view may be the result of such concentration because production and distribution from one or different media is gathered in one's hands and control over information may take place. Decrease in independent media owners' diversity, brings forth decrease in representation of multiculturalism, in the form of limited local community news; advertising in the related themes is also another consequence (Hiller, Savage, & Waldman, 2015).

Thus, high result of media ownership concentration is a dimension that may influence content diversity and advertising expenditure. When there is high concentration, program and/ or content media homogeneity may take place. This is further translated in decrease in sales of advertising time and space to advertisers. Whatever is saleable, survives and representation of different points of view may not be heard since the small group that may be interested in these points do not add up financial numbers for the big organizations. Media concentration may thus, influence content diversity with regard to program content and can be a threat to the freedom of expression (Leandros, 2010). It may also lead to a decrease in audiences' viewership due to their disinterest in homogeneity and further, a vicious circle is created because the advertising budgets are minimized. High ownership levels influence source diversity and existence of different opinions. Ownership consolidation reduces diversity and research on 1600 editorial positions in 25 top newspapers in USA illustrated stability in divergences of opinions after major mergers and acquisitions took place in the media sector (Ho & Quinn, 2009).

USER GENERATED CONTENT, COMMUNICATION TECHNOLOGIES AND MEDIA PLURALISM

Traditional media such as television and press may address a large audience in a short period of time on a daily basis (Belch & Belch, 2014). The advent of new communication technologies and the presence of electronic media, those operating namely online such as social networking sites that create and deliver content online, adds more material to the already existing media sources. Social media are associated with mobile and web applications that promote online user generated content that is created and is uploaded by users (Kaplan, 2015). Social media contain a wide range of online, word of mouth created content that is presented on blogs, Internet discussions, social networking sites, boards and forums (Mangold & Faulds, 2009). This allows for diversity of content to exist since content is presented online by different media.

Social media, allow for the interactive user feedback from digital devices and traditional media seem to lose ground in regard to the websites and online platforms. In order to have a more holistic approach, communication strategies that connect both traditional and online media take place. There is connection of the print era with the digital one for example and this is implemented taking into consideration tools that measure the medium's effectiveness and data analytics (Schlesinger & Doyle, 2015) to see whether combining traditional and new media is an effort worthy to be followed. The combination of print and digital content consists of a new business model that is implemented in different countries and is of particular significance especially when issues about countries' definition as independent states exist (Scotland, Quebec, Catalonia) (Schlesinger & Benchimol, 2015). Minorities and all voices need to be heard when the print press shrinks and digital press provides the forum to do so with the user generated content that is created.

Technological advancements in information and communication technologies have enabled the creation of online material that is widely spread in the digital world and is easy to access. They allow the presence of new content creators who emerge and distribute content in different media platforms and social networking sites that are 24 hours available (Leuven et al., 2009b). Media type information plays a significant role in media consumption that should be taken into account in combination with the fact that people consume differently on social networking sites (Choi, 2016).

New media platforms and streaming video services via video platforms may have an effect on the TV and video firms (Gimpel, 2015). Such implementation via information and communication technologies, allows for the consumption of media content at a different pace than that with the traditional media (Choi, 2016). A new e-culture is created where viewers may download videos from Apple iTunes via a search engine and a file transfer system, news content and TV programs from their mobile devices. 'TV everywhere' is being introduced (Waterman, Sherman, & Ji, 2013). Advertising agencies and media content producers need to take these challenges into account.

At the same time, technological developments can be a threat to pluralism (K.U. Leuven, 2009a). While more ideas and points of view exist in regard to media content, people tend to focus on ideas that are similar to those they share, creating groups of like minded people (Ntalianis, Kavoura, Tomaras & Drivas, 2015). Thus, pluralism does not really operate even if information and communication technologies offer ground to so in the sense that different points of view are not really heard. Online users can be engaged within a process of myopic dialogue and connect with those ideas and points of views that initially shared.

Deregulation, caused by the freedom of markets and the advent of new technologies that contributes so that every communication message can be on air or rather online, is not without problems. Freedom of expression allows for

many different voices to be heard, nonetheless, more players and new content come to the table. This, though, means, that the advertising pie will be divided in different market shares, a pie that diminishes because the new groups that will consume the programs are small and thus, not worth the advertising budget according to the financial estimates of the organizations. Having said that, diversity of sources and resources may influence the allocation of the advertising budget leading to its shrinkage. Papathanasopoulos argued for the role of advertising as a factor that influences what is broadcasted since new content is created on the basis that it can be sold, thus, influencing content diversity (Papathanasopoulos, 2005). New media have multiplied the creation of user generated content and is broken into small pieces.

User generated content can be uploaded in online communities, online websites, blog posts, social media profiles. Apart from the combination of print and digital as a new business communication model presented above, another business communication model that has been recently adopted since user generated content has made a powerful presence in media, is the integration and creation of a dialogue around the online user generated content material that is created by a competitive media channel or platform for a specific media program. This may act as a response to the existence of content diversity in media where viewership of user generated content of competing cable news shows in USA was found to be significant (Sabnis & Grewal, 2015).

SOCIO CULTURAL PROCESSES AND MEDIA PLURALISM

Content diversity in media based on socio-cultural and language issues of a geographic area consists of another important factor that may influence media plurality. Media programmes and their content may reflect the special language needs of different groups. Culture may act as a mechanism of social integration and community cohesion

in modern European cities (Kavoura & Bitsani, 2014). If we take into consideration that diversity may be in need due to the migrations that take place in Europe from Asian countries, then, we may realize the significance for the creation of media content that caters for those groups' needs. Migration is not a new phenomenon, yet, the tendency not to represent migrants in media exists in some countries. News associated with migration is depicted as something negative. Taking Poland as an example, 1% of its population is Polish, yet, stories and news coverage associated with different ethnicities are not covered (Triandafyllidou & Ulasiuk, 2015).

Best cases of cities like Barcelona and Copenhagen that aim to incorporate matters in a bilingual way so that everyone is represented (Guidikova, 2015; Schlesinger & Benchimol, 2015) are worth adopting. Issues of legislation need to be acknowledged, taking into account European institutions such as the European Broadcasting Union (Triandafyllidou & Ulasiuk, 2015).

In regard to Greece, the only recognized minority by the Greek state is a religion one (the Muslim population of Thrace) although in the Greek national elections in 2015, all three Parliament positions were won by Muslim candidates. Nonetheless, there are still not TV channels of national coverage recognized as minority media in Greece (Brogi & Dobрева, 2014). The above-mentioned minority is not represented, there is space for heterogeneity in the media content to be created, this though, has not taken place in the Greek media environment, yet.

The political system also influences media pluralism. Taking into consideration the action of banning of 2 channels from broadcasting one month before the parliament elections as an effort to silence opposition media in another continent, Asia in the country of Turkey (Toksabay & Solaker, 2015) is typical to note that based on political reasons, diversity on such TV content, news programs for example, is limited. Political diversity and media policies go hand in hand with the political stability and freedom of media that

in turn influences diversity in media content. Cultural interference in media pluralism may be also found in the People's Republic of China, where Facebook, one of the most popular social network websites, is currently banned (Riley, 2014).

The technological advancements and user generated content can be used as a platform of expression of free opinions nonetheless, democratic procedures are not always safeguarded. Costa Rica, Latin America, consists of another case, that illustrates how politicians may intervene in the media content since it did not have media pluralism for a period of 10 years -from 2002 till 2011 (Guerrero, 2015).

Geographical and geopolitical issues associated with a country may also influence the way media diversity is enforced. Taking the Cypriot Democracy as an example, - that is united and divided at the same time, half Cypriot, half Turkish due to the Turkish invasion in 1974-, Cypriot media life has been influenced and thus, programming as well. The official languages of the Cypriot Democracy are the Greek and Turkish (article 3, paragraph 1) and programs are transmitted in both Greek and Turkish (article 171, paragraph 1) based on the 1960 Cypriot Institutional legislation. Another typical example is the rapid expansion of Hispanics in the United States that illustrates how multiculturalism is a necessity to be taken into account since there are 45 million Hispanophones who speak Spanish as a first or second language in the United States (Shumow & Vigon, 2015). Examining the issue of language in regard to whether there is media content that represents these people's points of view and the need to be informed in in their own language, allows for media pluralism to exist and flourish.

Activities that deserve to be promoted and implemented by media are those similar to the ones initiated by Google. In late 2015 and following the migration wave of people from Asia to Europe, Google has asked people to contribute to a multilingual site with useful information for refugees and migrants (Fuller, 2015). Applica-

tions exist and can be implemented with the use of mobile devices for the defense of freedom of expression and of rights of all people.

ECONOMIC CONSIDERATIONS AND MEDIA PLURALISM

Media pluralism is also in close connection with the economic environment within which media content is created and distributed. Different kinds of programs need to represent the choices of different groups of people and this is an asset of the pluralistic approach of a society. This may not be the case in periods of economic recession due to high media production costs that in turn limit the range of content programming but may also control the independence of public service broadcasting.

In Greece, that is under deep economic crisis, local private channels broadcast the same content with that of national private channels. Thus, representation of local and regional interests is far from being catered. The New Greek TV, Radio and Internet Broadcast (NERIT), the Greek national public service media station that aims to promote different genres and types in its program, does not always succeed in acting independent due to its limited financial budget and funding that mainly comes from the Greek state. In a period of socio-economic crisis, allocation of resources is limited and thus, quality of content is underrepresented. Lack of financial resources to allocate to public service media is associated with lack of variety content programming. Thus, phenomena like the one described below may take place: the teaser for Mundial in NERIT's athletic program titled "our national team on the left (foot) in Mundial", - that was on air when the Greek team lost-, was negatively criticized by the president of the Greek Parliament from the leftist party Ms Konstantopoulou who mentioned that the use of the word 'left' implied negative connotations for the leftist party she belongs (T.X., 2015). This consists of an obvious attempt to censor freedom of speech and

media content as a time when NERIT's funding comes from the annual Greek budget.

Economic factors may thus, influence new productions where copy costs in producing media content require huge investments that do not exist (K.U.Leuven, 2009a).

RECOMMENDATIONS TO AGENTS INVOLVED IN THE IMPLEMENTATION OF MEDIA PLURALISM

Media pluralism needs the contribution of all to succeed its implementation. Interactions between market agents, policymakers, media are necessary.

- Policymakers at national and international level need to enforce regulatory frameworks to safeguard media pluralism for the media content that is created.
- Media channels and producers need to enforce freedom of expression. Productions that are created need to respect minorities and all points of view while media synergies and alliances can be further explored to deliver media content based on the latest and emerging technologies.
- Media professors may enforce the code of ethics in communication among potential media managers.
- Firms that operate in environments where socio-economic and political instability exists that may influence media pluralism may make the necessary arrangements to ensure that all points of view are heard. Sponsoring activities by means of financing productions and groups for the creation of multilingual TV programmes or the digital representation of different ideas regarding minorities and other underrepresented groups is an activity towards this end.
- Users of online media need to be active and create user generated content that represents many different points of view.

MEDIA PLURALISM: WHERE NEXT? FUTURE RESEARCH DIRECTIONS

Even if democracy exists in a country, it is not definite that the regulatory framework will prevail towards safeguarding media plurality. Inability and unwillingness by politicians and populations to institute reliable regulative mechanisms in public and private sectors (Gantzias, 2014). Research needs to take place at national level in countries that undergo socio-economic and political crisis at to the way plurality is understood within such frameworks.

Further research should take place on the initiation of television content diversity to represent migrants and/or minorities. Issues of language and diversity but also of multiculturalism need to be taken into consideration. Research is welcome for different ethnicities such as the anticipated creation of the federal state consisted of Cypriots and Turks to add to the literature in regard to issues of media content, language and association of ideas of those populations involved. At the time of writing this chapter, the peripheral parliament in Catalonia, Spain approved a 'solemn resolution' declaring the start of a formal process leading to independence (Buck, 2015). Thus, multiple cases offer ground form further research to take place.

Furthermore, future research is also encouraged based on the populations of migrants and refugees who move from one country to live in other countries, have money to spend, yet, the existing multicultural issues need to be acknowledged. Marketers should know the environment and special needs in order to be able to effectively manage their advertising campaigns.

Media regulatory policies are necessary to be implemented. The specificities of media markets of relatively young media markets within the EU members (K.U.Leuven, 2009a) or the socio-economic and cultural crisis that countries may undergo, brings forth the significant issue of the role of the environment and the effect it has on media pluralism. Therefore, research on these

markets may also add to the literature on media plurality.

Video platforms can be an alternative way for generation of media content and media types. Pay TV services offer the possibility to the viewer to stream premium video, an issue that should be further examined.

The incorporation of the competitors' comments as user generated content to programs on television was found to increase the viewership (Sabnis & Grewal, 2015). Programs could take into consideration such a contemporary communication strategy that creates a dialogue and defends media diversity by adding competitors' points of view to their own material.

Combining media content, print and digital, as a new business communication model (Schlesinger & Doyle, 2015; Schlesinger & Benchimol, 2015), with the contribution of information and communication technologies, can be another alternative communication strategy for preserving media pluralism and this needs to be further researched. Research on advertising media planning that incorporates the combination of traditional and online media content to its strategic decisions is also in need rather than examining them separately, in contrast one to the other.

CONCLUSION

Technological advancements in regard to the creation of media content and user generated content that is available online, offer new opportunities so that web technologies can guarantee freedom of expression of many different voices.

This chapter adds to the existing literature on media communication by highlighting emerging trends that bring media pluralism's dimensions under continuous social negotiation. The socio-economic and political environment needs to be considered to safeguard that the constituent elements and dimensions of media plurality are implemented under the continuous renegotiation that takes places.

KEY TERMS AND DEFINITIONS

Concentration of Media Ownership: Ownership of different media usually but not necessarily after mergers and acquisitions that brings forth the issue of representativeness and freedom of expression and lack of presence of different points of view because production, distribution from one or different media is gathered in one's hands and control over information may take place.

Content Diversity: Production of a variety of material for media consumption that is consisted of a variety of content that is different one from the other.

Media Pluralism: Safeguarding representation of different points of view so that numerous people and opinions have an equal chance to be heard, read, broadcasted on media.

Online Video Platform: A media type service that allows users to search, file, upload video content on the Internet that requires subscription.

Social Media: Ways of interacting among people using web online information and communication technologies.

Socio Economic Processes: Related to social and economic issues, identifying social and economic needs within a community and the creation of strategies to address those needs.

User Generated Content: Any form of online content that is created and distributed by consumers and users.

Bipolar Model in Collective Choice

Ayeley P. Tchangani

Université Fédérale Toulouse Midi-Pyrénées, France

INTRODUCTION

Collective choice is a sub-domain of decision analysis (a discipline comprising the philosophy, theory, methodology, and professional practice necessary to address important decisions in formal manner according to Wikipedia) that addresses decision making problems where a certain number of decision makers must select a subset (possibly reduced to a singleton) of alternatives from a large set of potential alternatives in order to achieve some collective as well as individual objectives, preferences, or desires. Such decision making problems are encountered in many practical situations such as management, engineering, economics, social, politics etc., see for instance (Bouyssou *et al.*, 2000), Steuer (1986), and references therein for some real world applications even though in these references the problems are most of the time treated as a single decision maker problems. The existence of many decision makers necessitates to have a *coordination mechanism* (how to aggregate the view points of all decision makers) to address collective choice problems. The purpose of this chapter is to address such coordination mechanism. Using bipolar analysis that consists in evaluating alternatives by two opposite measures (a measure gathering positive aspects of the alternative and that resuming its negative aspects) with regard to pursued objectives at individual level as well as at community level permits in some extent to embed human attitude into the decision process.

The remainder of this chapter is organized as follows. In the second section a background on (collective) choice problems resolution methods will be recalled; then the main focus of this chapter will be presented in third section; section four will be dedicated to the main contribution of

this chapter: bipolar framework for modeling and solving collective choice problem; section five presents a sketch of future directions researches; a conclusion is presented in section six and finally references, additional reading, and some keys terms and definitions end the chapter.

BACKGROUND

In political science, methods for realizing a collective choice (mapping individual preferences onto collective preferences) are dominated since the advent of democracy by simple majority voting process (Picavet, 1996). But many theoretical results such as that of Borda, see (Borda, 1781), Arrow impossibility theorem (Arrow, 1951) show that this way of aggregating individuals preferences can lead to inconsistency. In decision analysis, that actually does have many steps such as formulating decision goal or objectives, identifying attributes that characterize potential alternatives that can respond to the decision goal and making recommendation regarding these alternatives given the decision goal, choice is the final step. But to choose, one must evaluate first; the construction of an evaluation procedure, often carried up by an expert known in the literature as the analyst (Bouyssou *et al.*, 2000) is an important step in the decision process; this step is the main purpose of this chapter. This construction consists in aggregating individual preferences, understood in a broad sense to obtain a way that permits to rank, at least partially, different potential alternatives. Classically, two main approaches have dominated evaluation process in modern decision analysis: value or utility type approach (a value function or an utility measure is derived for each

DOI: 10.4018/978-1-5225-2255-3.ch633

alternative to represent its adequacy with decision goal), see for instance Steuer (1986) and Saaty (1980); outranking methods (a pair comparison of alternatives is carried up under each attribute or criteria to derive a pre-order over the alternatives set), see (Bouyssou *et al.*, 2000), (Brans *et al.*, 1986, 1986a). The approach that will be described in this chapter can be considered as an intermediate one compared to those two approaches evoked previously; indeed by using numerical values to evaluate alternatives look like utility type approach, but as two “opposite” measures are used, it permits incomparability as it is the case in outranking approaches.

MAIN FOCUS OF THE ARTICLE

In many situations, collective decision making is made through a majority voting process where each decision maker casts a ballot for only one alternative and the alternative that obtains the maximum of voices is considered as the community choice. But voting process does not capture in our opinion all attitudes of human beings such as ambiguity, indecision, social values consideration, etc. Indeed, decision makers often face uncertainties (impossibility of decision makers to clearly express their objectives, to elicit and assess attributes, etc.) and interactions (a decision maker may be influenced by other decision makers when expressing his or her judgment). Furthermore, French mathematician Jean-Charles de Borda and other have noticed since 18th century that in an election where the winner is the candidate who got the majority of votes and where there are more than 3 candidates, candidate who obtains the majority of voices is not necessarily the preferred one by the majority of voters. In this chapter we adopt an approach that highlights *bipolarity notion* between all components of collective decision analysis problem. We are motivated by the fact that cognitive psychologists have observed for long time that human evaluate alternatives by considering separately their positive aspects and

their negative aspects, see for instance (Caciopo & Berntson, 1994) and (Osgood *et al.*, 1957). To this end, we introduce *supporting* and *rejecting* notions (Tchangani, 2010) that relate attributes to objectives leading to an evaluation model in terms of two measures or indices (selectability and rejectability) for each alternative in the framework of satisficing game theory (Stirling, 2003) so that a decision maker can be in position of not being able to discriminate between two alternatives. These notions permit to partition attributes set into three subsets given an objective: attributes that support this objective, attributes that reject this objective and attributes that are neutral with regard to this objective; of course only supporting and rejecting attributes are interesting for evaluation process. Selecting and rejecting degrees of an attribute with regard to an objective may be assessed using known techniques such as analytic hierarchy process (AHP), see (Saaty, 1980) or any method that could assign a measure to an attribute with regard to a pair of objective and alternative. This model allows alternatives to be characterized by heterogeneous attributes (at individual level) and possibly different attributes from an individual to another; it allows also incomparability between alternatives in terms of Pareto-equilibrium, see (Pareto, 1896). Collective decision making situations with such issues are pervasive in real world applications; for instance a government evaluating projects that belong to different domains such as health, infrastructures, social, economics, etc. with the main objective to enhance a country developing process (Tchangani, 2015). In such situations, though attributes characterizing projects may be completely different, the important thing is their adequacy with regards to the pursued objectives, so that alternative projects can be ultimately compared on the same basis (decision maker’ desires). The social influence between decision makers and decision makers’ attitude will be taken into account through different degrees such as concordance/discordance degrees within the group, selfishness degree, risk averse degree, see (Tchangani, 2014). When making decision in complex situation, it

is rather rare that a human reach a final decision without hesitation; most of the time there exist some dubitative attitude, some indecision between several possible alternative decisions; this attitude is carried up in this chapter through satisficing game (Stirling, 2003).

BIPOLAR APPROACH FOR SOLVING COLLECTIVE CHOICE PROBLEM

Modeling Process

Formerly, collective choice problem is described by following elements: a set U of potential alternatives from which an alternative or a subset of alternatives must be selected by a group of decision makers; a generic decision maker is designated by i and a generic alternative by u ($u \in U$). In the bipolar analysis framework, evaluation process consists in determining for each alternative $u \in U$, two measures known as *satisfiability* measures: namely a *selectability* measure denoted $\mu_{S_i}(u)$ derived by decision maker i or $\mu_S(u)$ derived by the community of decision makers or stakeholders and a *rejectability* measure denoted by $\mu_{R_i}(u)$ derived by decision maker i or $\mu_R(u)$ derived by the community. The modeling process adopted in this chapter goes from individual to global, global satisfiability measures $\mu_S(u)$ and $\mu_R(u)$ will be obtained by aggregating individual satisfiability measures $\mu_{S_i}(u)$ and $\mu_{R_i}(u)$ over all decision makers. Locally each decision maker i may wish to satisfy own objectives or desires; to this end he or she will use a set of features, criteria or attributes to evaluate the adequacy of an alternative with regard to his or her objectives; these sets may be common to all actors for some particular choice problems but it is not an obligation for the choice procedure being developed in this chapter. We propose to elicit satisfiability measures in two steps: firstly, each decision maker i will derive its categorical

(that is without taking into account the existence of other members) satisfiability measures $\mu_{S_i}^0(u)$ and $\mu_{R_i}^0(u)$ for each alternative $u \in U$ using BOCR analysis for instance. The convergence of *supporting/rejecting* notions and uncertainty leads to an analysis framework known as BOCR analysis, see (Tchangani, 2010; Tchangani, 2015) that may constitute an interesting alternative method for elicitation and evaluation. In this framework the set of attributes characterizing an alternative with regards to an objective is divided into four subsets: benefit subset (B) (certain attributes of alternative that support the objective); opportunity subset (O) (uncertain attributes of alternative that support the objective); cost subset (C) (certain attributes of alternative that reject the objective); and risk subset (R) (uncertain attributes of alternative that reject the objective). Final evaluation of alternative u with regards to objective o will be obtained by aggregating separately positive aspects in terms of benefit and opportunity and negative aspects in terms of cost and risk to measure how well is this alternative with regard to that objective and opposite forces in the realization of that objective by this alternative respectively. Let us denote by $b_k^o(u)$, $o_k^o(u)$, $c_k^o(u)$ and $r_k^o(u)$ the normalized values of benefit, opportunity, cost and risk attribute k of alternative u with regard to objective o ; and by $b^o(u)$, $o^o(u)$, $c^o(u)$, and $r^o(u)$ vectors gathering these normalized benefit, opportunity, cost and risk measures respectively. Let suppose that decision maker is able to supply for these components normalized relative degrees vectors in terms of ω_b , ω_o , ω_c , and ω_r ; then the overall benefit, opportunity, cost, and risk measures of alternative u for objective o are obtained by aggregating over the corresponding attributes set using Choquet integral associated to a weighted cardinal fuzzy measure for instance, see (Tchangani, 2014), as shown by the expressions of Table 1.

In Table 1, $C_\omega^{wefm}(x)$ stands for Choquet integral of numerical vector x associated to a

Table 1. BOCR components for objective o

$B^o(u) = C_{\omega_b}^{wcfm}(b^o(u))$
$O^o(u) = C_{\omega_o}^{wcfm}(o^o(u))$
$C^o(u) = C_{\omega_c}^{wcfm}(c^o(u))$
$R^o(u) = C_{\omega_r}^{wcfm}(r^o(u))$

weighted cardinal fuzzy measure with relative importance weights vector ω of elements to aggregate, see Table 2 and (Tchangani, 2013).

Indeed, given the synergy created by grouping attributes by category, Choquet integral with a weighted cardinal fuzzy measure is well suited as an aggregation operator. Let us denote by $b(u)$, $c(u)$, $c(u)$ and $r(u)$ vectors gathering benefit, opportunity, cost and risk measures with regard to all objectives and by ω^o , the relative importance vector of objectives then the overall opinion regarding the alternative u is captured by the benefit measure $B(u)$, opportunity measure $O(u)$, cost measure $C(u)$, and risk measure $R(u)$ will be obtained similarly by aggregation as shown in Table 3.

Categorical selectability measure $\mu_{S_i}^0(u)$ and categorical rejectability measure $\mu_{R_i}^0(u)$ of alter-

native u in the point of view of decision maker i are finally obtained by normalizing over the alternatives set U , the measures

$$\phi_i B(u) + (1 - \phi_i) O(u)$$

and

$$(1 - \phi_i) C(u) + \phi_i R(u),$$

as shown by expressions of Table 4, see (Tchangani, 2014).

Parameter $0 \leq \phi_i \leq 1$ in Table 4 can be interpreted as the risk averse index of actor i ; indeed, this index permits to adjust the attitude of a decision maker toward uncertainty; for instance a risk averse decision maker, for who $\phi_i \rightarrow 1$, will balance immediate benefit (B) with potential harm (R) regardless of potential benefit (O) and immediate cost to pay (C).

In collective decision analysis situation, there is always some *conditionality* in the sense that the preferences of a given decision maker may be conditioned to that of other decision makers because when making decision, a decision maker may be influenced by its social vicinity positively or negatively. Indeed, influence does not mean positive perception (altruism, deference) of

Table 2. Choquet integral associated to a weighted cardinal fuzzy measure

Given a n dimension numerical valued vector x and a relative importance vector ω of the elements of x, the Choquet integral $C_{\omega}^{wcfm}(x)$ of x associated to a weighted cardinal fuzzy measure with relative importance vector ω is given by $C_{\omega}^{wcfm}(x) = \sum_{k=1}^n \left\{ \left(\frac{n - (k-1)}{n} \right) \left(\sum_{j \in A_k} \omega_j \right) (x_{\sigma(k)} - x_{\sigma(k-1)}) \right\}$ where σ is a permutation over the elements of x given by: $x_{\sigma(1)} \leq x_{\sigma(2)} \leq \dots \leq x_{\sigma(n)} \text{ and by convention } x_{\sigma(0)} = 0$ and A_k is defined by: $A_k = \{\sigma(k), \sigma(k+1), \dots, \sigma(n)\}$
--

Table 3. BOCR components for alternative u

$$\begin{aligned} B(u) &= C_{\omega_o^{wcfm}}^{wcfm}(b(u)) ; O(u) = C_{\omega_o^{wcfm}}^{wcfm}(o(u)) \\ C(u) &= C_{\omega_o^{wcfm}}^{wcfm}(c(u)) ; R(u) = C_{\omega_o^{wcfm}}^{wcfm}(r(u)) \end{aligned}$$

the influenced decision maker toward influencing one; it may represent repulsion or aggressiveness. One can admit that if two decision makers are in discordance then the conditioned selectability of one should be proportional to the categorical rejectability of the other and in the case they are in concordance it must be proportional to the categorical selectability of the other decision maker; a similar observation holds for the rejectability, see (Tchangani, 2014). So let denote by $\mu_{S_i/V(i)}$ and $\mu_{R_i/V(i)}$ the conditional selectability and rejectability of decision maker i given his position with regard to his social vicinity ($V(i)$) and by $\mu_{S_{V(i)}}^0(u)$ and $\mu_{R_{V(i)}}^0(u)$ the vector of categorical selectability measures and rejectability measures of all member of social vicinity of this decision maker. The measures $\mu_{S_i/V(i)}(u)$ and $\mu_{R_i/V(i)}(u)$ are therefore obtained by aggregation of categorical satisfiability measures and normalization as given in Table 5.

In expressions given in Table 5, the attitude of decision makers is taken into account with regard to his/her vicinity through relative concordance weights vector ω_i^c and discordance weights

Table 4. Categorical satisfiability measures

$$\begin{aligned} \mu_{S_i}^0(u) &= \frac{\phi_i B(u) + (1 - \phi_i) O(u)}{\sum_{v \in U} \{ \phi_i B(v) + (1 - \phi_i) O(v) \}} \\ \mu_{R_i}^0(u) &= \frac{(1 - \phi_i) C(u) + \phi_i R(u)}{\sum_{v \in U} \{ (1 - \phi_i) C(v) + \phi_i R(v) \}} \end{aligned}$$

vector ω_i^d ; see (Tchangani, 2014). Weighting parameter $0 \leq \gamma_i \leq 1$ can be interpreted as the altruist degree of decision maker i ; indeed, $\gamma_i \rightarrow 1$ means the total altruist behavior of decision maker i as he does not consider the contribution of his discordance attitude in the formation of his conditional satisfiability measures whereas $\gamma_i \rightarrow 0$ corresponds to the case where decision maker i behaves aggressively as he considers only his discordance attitude about the opinions of the members of his vicinity.

The ultimate selectability measure $\mu_{S_i}(u)$ and rejectability measure $\mu_{R_i}(u)$ of the alternative u in the opinion of decision maker i are corrected as shown by expressions of Table 6 where $0 \leq \delta_i \leq 1$ is the selfishness degree of decision maker i .

Final choice procedures will be derived from the ultimate and individual satisfiability measures; basically two main procedures may guide how to reach a collective choice: reasoning from an “ag-

Table 5. Conditional satisfiability measures

$$\begin{aligned} \mu_{S_i/V(i)}(u) &= \frac{\gamma_i C_{\omega_i^c}^{wcfm}(\mu_{S_{V(i)}}^0(u)) + (1 - \gamma_i) C_{\omega_i^d}^{wcfm}(\mu_{R_{V(i)}}^0(u))}{\sum_{v \in U} \{ \gamma_i C_{\omega_i^c}^{wcfm}(\mu_{S_{V(i)}}^0(v)) + (1 - \gamma_i) C_{\omega_i^d}^{wcfm}(\mu_{R_{V(i)}}^0(v)) \}} \\ \mu_{R_i/V(i)}(u) &= \frac{\gamma_i C_{\omega_i^c}^{wcfm}(\mu_{R_{V(i)}}^0(u)) + (1 - \gamma_i) C_{\omega_i^d}^{wcfm}(\mu_{S_{V(i)}}^0(u))}{\sum_{v \in U} \{ \gamma_i C_{\omega_i^c}^{wcfm}(\mu_{R_{V(i)}}^0(v)) + (1 - \gamma_i) C_{\omega_i^d}^{wcfm}(\mu_{S_{V(i)}}^0(v)) \}} \end{aligned}$$

Table 6. Individual satisfiability measures

$$\begin{aligned}\mu_{S_i}(u) &= \delta_i \mu_{S_i}^0(u) + (1 - \delta_i) \mu_{S_i/V(i)}(u) \\ \mu_{R_i}(u) &= \delta_i \mu_{R_i}^0(u) + (1 - \delta_i) \mu_{R_i/V(i)}(u)\end{aligned}$$

gregation” of individual satisfiability measures or from individual short lists obtained locally using individual procedures.

Solution Procedures

Given the idea of going from individual preferences to community preferences considered here, to reach a community level solution one can consider two possibilities: obtaining an aggregated satisfiability measures and then analyzing the selection problem as a single decision maker problem, or obtaining short lists of local satisficing equilibrium alternatives and then trying to converge to a community satisficing alternative(s).

Aggregated Satisfiability Measures Approach

Let denote by $\mu_S(u)$ and $\mu_R(u)$ the aggregated selectability and aggregated rejectability measures of alternative u obtained from individual measures of all decision makers. Arguing that selected or rejected alternative by two decision makers is sounder than selected or rejected alternative by one decision maker appeals for a synergetic aggregation scheme such as Choquet integral considered in previous sections. Once these measures are obtained, the analysis process in order to reach a final decision can rely on indicators built upon a value function

$$\pi(u) = v(\mu_R(u), \mu_S(u))$$

such as: maximum discriminant,

$$\pi(u) = \mu_S(u) - q\mu_R(u);$$

maximum boldness, $\pi(u) = \frac{\mu_S(u)}{\mu_R(u)}$; maximum selectability index or minimum rejectability index, $\pi(u) = \mu_S(u)$ or $\pi(u) = \frac{1}{\mu_R(u)}$ respectively.

Convergence From Local Analysis

Instead of aggregating individual satisfiability measures to reason on a single decision maker basis, one may consider that each decision maker i comes with his own selected subset of satisficing equilibrium alternatives $\mathcal{E}_{q_i}$ obtained by balancing his selectability and rejectability measures up to a caution or boldness index q_i (Tchangani, 2014). If it happens that a common alternative belong to all subsets, it constitutes the consensus alternative and the choice problem is solved. But this will constitute an exceptional situation and in most cases, local best alternatives will differ from one decision maker to another so that an adequate mechanism is needed to reach a final decision. In this case, one possibility is to define a score $v(u)$ over these individual selected subsets; some possible such scores are given in Table 7 where 1_Ω is the indicator of the set Ω given by

$$1_\Omega(x) = \begin{cases} 1 & \text{if } x \in \Omega \\ 0 & \text{if } \text{not} \end{cases}$$

Table 7. Global score for alternatives

$$\begin{aligned}v(u) &= \prod_{i=1}^n \left\{ \frac{\mu_{S_i}(u)}{\mu_{R_i}(u)} \right\} \\ \text{or} \\ v(u) &= \sum_{u \in \Sigma_{q_i}} \left\{ 1_{\Sigma_{q_i}}(u) \right\}\end{aligned}$$

It may happen (for sake of simplicity for instance) that decision makers be disposed to choosing by a voting process; this case is considered in the following subsection.

Choice by Voting: BORDA Revisited

Choice by voting generally consists in a simple procedure where each decision maker gives his voice to only one alternative and at the end the alternative that obtains the maximum of voices will be declared the winner. But this procedure does have some limitations; indeed, in his paper entitled « *Sur les élections au scrutin* » published in 1781 in « *Mémoires de l'Académie Royale* », see (Borda, 1781), the French mathematician Jean-Charles de Borda has shown that, in a majority election where there are more than 3 candidates, candidate who obtains the majority of voices is not necessarily the preferred one by the majority of voters. To overcome this situation, he proposed to choose the elected candidate using a merit order: each voter will rank candidates according to his preference by assigning, if there are m candidates, the score $m-1$ to the most preferred candidate, the score $m-2$ to next most preferred and so on until the score 1 to the last preferred candidate. So if there are n voters and denoting by $\omega_i(j)$ the score assigned to candidate j by voter i , then the global score or merit $\omega(j)$ of candidate j is obtained by adding all of its scores as given by the expression $\omega(j) = \sum_{i=1}^n \omega_i(j)$ and the elected candidate will be that who got the most important merit score.

But in practice, for a given candidate, a particular voter may have positive opinion for some aspects of that candidate and negative opinion for other aspects. So Borda's voting procedure means that each voter must do a balance of his opinions (positive and negative) in order to obtain a sort of global merit score for each candidate before voting. But it is well known that it is easier to aggregate homogeneous aspects (positive for instance) than heterogeneous aspects (combining

positive and negative aspects simultaneously). So we propose, building on the bipolar notion, a voting process according to the following scheme: voter i will rank all candidates according to their positive aspects in his opinion to obtain a global positive merit score $\omega_i^P(j)$ for candidate j and then rank them according to their negative aspects to obtain a global negative merit score $\omega_i^N(j)$. The final choice process can be done using two different procedures: selection from individual choice (a global merit score $\omega(j)$ for candidate j is obtained similar to expressions of Table 7) and selection from aggregated scores (voters opinions are aggregated separately to obtain for a given candidate j , a global positive merit score $\omega^P(j)$ and a global negative merit score $\omega^N(j)$ and then obtain the global score by balancing $\omega^P(j)$ and $\omega^N(j)$).

Decision regarding which procedure must be used in a particular case, how to aggregate positive and negative opinions separately as well as how to make trade-off between such aggregated opinions, are upper level and law oriented issues that regulate life in community such as a constitution in democratic nations.

FUTURE RESEARCH DIRECTIONS

Decision making approach described in this chapter falls into soft computing paradigm. If bipolar approach presented in this chapter permits to reach possibly robust solution, there remains, nevertheless, possible improvements regarding methodologies and modeling tools in order to reach usability of this framework in solving real world complex problems. Here are some possible improvements directions.

- **Context:** How decision makers and/or experts view positive and negative aspects of an alternative on one hand and their attitude towards risk on other hand may depend on their personal situation as well as

the behavior of decision environment that we refer to as the context. Indeed, preferences depend upon psychological attributes of the person who judges; therefore to dispose of a framework that is as close as possible to human way of deciding, this context component should be considered in modeling stage.

- **Dynamics:** As the context sensitive consideration mentioned above, attitude of decision makers and/or experts may vary from one instant to another so that a same problem may be viewed differently by the same decision maker from an instant to another. This dynamicity should be considered in the modeling process to allow parameters variation at each instant; mainly if a computer assisted tool to support the decision process must be developed.
- **Sensitivity Analysis:** Considering context and actors psychological attributes and interactions appeal for developing a way to do a sensitivity analysis with regards to these parameters. This sensitivity analysis may result in realizing scenarios analysis and answering questions like “what if?” and/or “is it possible?”.

CONCLUSION

Collective choice problem as a decision making problem where possibly antagonistic preferences of many actors or stakeholders have to be taken into account is considered in this chapter. Indeed, the main purpose of this chapter has been to propose a modeling process of collective choice that cope as much as possible with individual behavior in early stages of the decision process, collectivity issues being postponed as much as possible in later stages. The proposed approach of this chapter relies on the cardinal concept or notion of bipolarity at the individual as well as community level. This concept consists in evaluating (individually or collectively) each potential alternative or can-

didate by two measures: a measure that reflects positive aspects of the considered alternative and a measure that gathers its negative impacts with regard to the pursued goal(s). It has also been shown that even classical choice using voting (by merit as proposed in 18th century by Borda) process can be formulated in this framework to integrate individual preferences as much as possibly into the community choice process.

KEY TERMS AND DEFINITIONS

Aggregation: A process that permit to go from data represented in a high dimension set to a representation in a set of low and compact dimension.

Bipolarity: A notion that consists, for an actor, in viewing or evaluating anything in two directions: a direction positively seen by the actor and a direction considered to impede his aspirations.

BOCR Analysis: A framework of decision analysis where potential actions, options, deci-

sions, or alternatives are evaluated through four indicators: benefit (B), their certain or immediate positive contribution to decision goal; their opportunity (O), the positive uncertain or long term contribution; cost (C) that summarizes their immediate or certain aspects that work against the achievement of decision goal; and risk (R), an indicator that aggregates uncertain or long term potential threats.

Collective Choice: A decision making problem where a certain numbers of actors, decision makers, stakeholders or players must choose a subset (possibly reduced to a singleton) of alternatives or actions among a large number of potential actions or alternatives in order to achieve some collective as well as individual objectives.

Coordination Mechanism: Process by which the views points of many decision makers are aggregated to address collective choice problems.

Majority Voting: A coordination mechanism in collective choice where each decision maker must pronounce himself over a single alternative and the alternative that obtains the maximum voices win.

Rejecting: A notion to express the fact that behavior of something (attribute for instance) is negatively correlated with that of another thing (objective for instance).

Satisficing Game: A decision analysis framework where each action or alternatives is evaluated over two measures or degrees: a *selectability* measure that works towards the achievement of decision maker goal and the *rejectability* measure that constitutes the cost, in a broad sense, to pay to achieve the goal.

Supporting: A notion to express the fact that behavior of something (attribute for instance) is positively correlated with that of another thing (objective for instance).

S

Censorship in the Digital Age the World Over

Kari D. Weaver

University of South Carolina – Aiken, USA

INTRODUCTION

Censorship is an issue that has impacted information access for as long as humans have shared information. As communication technologies have grown and changed, from oral traditions, to the printing press, to the rapid rise of the Internet, many have sought to limit the ability of others to create, find, use, and share information with their fellow citizens. This has had important implications for the power and freedom of individuals within these societies, and has helped to shape the face of the modern world.

Censorship is also of critical importance to managers and entrepreneurs worldwide. Although international business has become increasingly “flattened” by globalization, information policy varies widely from nation to nation and has a significant impact upon both business climate and personnel safety. Employees in some countries may not be able to receive or share certain information, and government censorship may require additional functionality to be included in products or services. Cultural norms, practices, and ethical guidelines for capturing and sharing information are governed by the laws of the host nation. All of these factors must be taken into account when considering expanding operation into new locations around the globe.

BACKGROUND

Although censorship is a familiar concept, a precise definition is challenging. In this article, “censorship” is defined as “the action or the use

of authority to limit access to information that would otherwise be available in the public sphere.” Common justifications for censorship include morality, obscenity, blasphemy, or national security. It can be and is performed by individuals, groups, corporations, or governments and their agents.

Censorship has existed throughout civilized history. The word “censor” is derived from Latin, when censors within the Roman Empire conducted the census and other state functions while regulating morality under Roman rule (Pina Polo, 2012). Censorship has been practiced worldwide, primarily through religious institutions or by governments acting as agents of the church. Book banning and burning has played an important role in European history, such as in France during the Enlightenment, in the USSR during the Bolshevik revolution, and in Germany during the Weimar Republic (Lyons, 2011). There were few laws regulating censorship of information until 1789, when the Constitution of the United States of America was adopted, and individual freedoms, including the right to free speech, became protected. Since then, similar laws have been adopted by other countries around the world (Passavant, 2002).

Today, information has become a digital commodity, and individuals are now affected both by the laws of their home countries and by international standards. This is further complicated as individual jurisdictions seek to apply laws from the offline world to the online context (Worstell, 2012). However, no overarching international laws directly address censorship, and it was only in 2011 that the United Nations Human Rights Council identified unfettered Internet access as a human right (La Rue, 2011). International law

regarding information theft lags behind even the UN report, as prosecutions are based on the laws of the countries in which the crimes were perpetrated. Depending upon the country, these laws can be extremely restrictive, very broad, or potentially even in violation of internationally-recognized human rights agreements (La Rue, 2011). This inconsistent treatment of information across countries, in concert with increasing technological complexity, has led to challenges with the implementation of new internet standards (DeNardis, 2009).

Educational institutions have historically had a special role within society, with libraries and universities acting as both repositories of knowledge and points of information access for their communities. Libraries are common targets for censorship since removing a book from a personal collection blocks access for one person, whereas removing it from the library blocks access for the whole community. As Byrne (2003) notes, librarians cultivate a “professional narrative of non-judgmental, disinterested provision of access to information” which “confers a legitimacy on their professional choices to make [information] available or not make available” (Byrne, 2003, p. 7). Libraries have historically taken all sides on censorship debates - sometimes removing materials, keeping them in place, or relocating them to special sections. Broadly, though, libraries tend to focus on preserving, protecting, and providing access to information, as can be seen in their central role in preserving culture in locations as varied as Afghanistan and Colombia (Knuth, 2003, 2006).

CENSORSHIP IN THE MODERN WORLD

Throughout the modern world, agents of censorship fit broadly into three categories: individuals, governments, and corporations. In countries with laws protecting freedoms of speech, religion, and the press, acts of censorship are typically initiated by individuals or corporations, while, in others,

authoritarian governments are the primary agents of censorship. Although China is most commonly associated with censorship, there is widespread agreement that governments in Eritrea, North Korea, Syria, and Iran are even more restrictive (Reporters Without Borders, 2013). Other countries, such as Ethiopia, Cuba, Saudi Arabia, and Belarus, are also often listed as “most censored” countries, but rankings depend on the perspective of the organization reviewing censorship activities in each nation.

Regardless of the censoring agent, there are three main strategies for censoring materials. The first is removal or blocking of offensive material, which prevents individuals from viewing or experiencing the material at all. As the most common form of censorship, this strategy is typically employed where information is contained within physical artifacts, such as books or recordings. Second, instead of removing the material directly, organizations may instead remove any references to the material, such as a catalog entry or its visibility to a search engine (Zittrain & Palfrey, 2008; Chen & Wang, 2010). This strategy may extend to keyword filtering at an internet service provider (ISP) or router level, depending on the level of control of the government organization (Xu, Mao, & Halderman, 2011). With the growth of the Internet and users’ dependence on search engines for finding information, this is often as effective as removing the information entirely. Another variant of this method is blocking certain search terms that may lead to the offensive material, such as is used with the Chinese microblogging platform Weibo (Ng, 2013). The final method is intimidation. Authoritarian regimes make it known through a variety of means that exploration of certain materials or ideas is forbidden and will carry consequences for the user. While the ultimate decision remains with the user, the potential for punishment may prevent the search from ever taking place.

Due to its rapid growth and power for sharing information, the Internet has proven an important battleground for censorship activity. While most

Western democracies impose only very limited restrictions on Internet content (such as on child pornography), some governments limit public access to certain websites or databases (Morozov, 2011). This is accomplished in multiple ways. First, nationally-owned network hardware at the main network connections for the country may be configured to filter out certain websites or information from specific IP address ranges (Joyce, 2010; Yang, 2009). Second, private companies that operate their own servers or networking equipment within the nation may be required to themselves filter or block certain information, websites, or address ranges (Piety, 2012). Finally the nation may actively employ censors who review Internet content, removing or blocking content that is deemed unacceptable (Joyce, 2010; Yang, 2009). Beyond governments, individuals in countries in the European Union also may self-censor personal information, asking search engines to remove content under the recent Google v. Spain “Right to be Forgotten” ruling in the European courts (Arthur, 2014).

In the corporate sphere, another important consideration is “net neutrality,” or the willingness to pass information to other systems in the global network independent of content, point of origin/destination, or interfacing equipment. While discussions in the United States have primarily been framed in commercial terms, requiring all ISP’s to provide all information equally to their subscribers, there are also significant implications to the free exchange of information worldwide (MacKinnon, 2012). Currently the United States Federal Communications Commission (FCC) is drafting a ruling to protect net neutrality and limit corporate censorship, becoming only the second country in the world to do so despite legal challenges from corporate interests (Selyukh, 2015). The FCC originally planned to recommend against adopting net neutrality, but reversed their decision after receiving significant public comment from U.S. citizens, largely following a viral video explaining net neutrality by comedian John Oliver (Brody, 2015). However,

the limited adoption of net neutrality legislation worldwide likely means this form of censorship is still possible, as the Internet’s infrastructure does not specify the path information must take, and it may pass through the infrastructure of a nation that does not support net neutrality (Subramanian & Katz, 2011).

CURRENT PERSPECTIVES ON CENSORSHIP

As with the difficulty in defining censorship, there are multiple interests and perspectives regarding censorship, both for and against it. Here is a review of the major perspectives, their motivations, and their impact.

For those opposed to censorship, a common perspective advocates the right of people to intellectual freedom and to access publicly-available information in an unrestricted manner. As stated by the American Library Association (ALA):

Intellectual freedom is the right of every individual to both seek and receive information from all points of view without restriction. It provides for free access to all expressions of ideas through which any and all sides of a question, cause or movement may be explored. (American Library Association, Office for Intellectual Freedom, 2013a)

ALA further explains their reasoning:

Intellectual freedom is the basis for our democratic system. We expect our people to be self-governors. But to do so responsibly, our citizenry must be well-informed. Libraries provide the ideas and information, in a variety of formats, to allow people to inform themselves (American Library Association, Office for Intellectual Freedom, 2013a).

In contrast to this perspective, many seek to limit the availability of information based on ideological perspective. For instance, according to Hilgers (1913):

In general, censorship of books is a supervision of the press in order to prevent any abuse of it. In this sense, every lawful authority, whose duty it is to protect its subjects from the ravages of a pernicious press, has the right of exercising censorship of books (p. 519).

In this light, censorship is viewed as a positive activity, counteracting a potential corruption of a message. According to Baker (1989), “suppression of dissident political views is likely to be the most common and most vigorously pursued form of censorship” (p. 34). This perspective also commonly arises in a religious context. Based on data collected by the American Library Association Office of Intellectual Freedom (2013b) since 1990, the fifth, sixth, and seventh most common reasons for book challenges in the United States are due to “the occult or Satanism,” “homosexuality,” and “religious viewpoint,” respectively. This has also been seen in circumstances where religion is prominent in the public sphere. In Afghanistan, the Taliban have repeatedly destroyed books or other artifacts that did not fit their religious beliefs (Knuth, 2006).

In other cases, censorship is sought because some believe the material does not meet a common standard of decency (Bean, Dunkerly-Bean, & Harper, 2014). A “community standard” is frequently invoked with topics involving sexuality, profanity, and violence. While generally limited, this approach has even extended to consumer agreements with mobile technology providers in countries from Peru to Kenya (MacKinnon, 2012). This standard is also commonly invoked in the context of child welfare, since publicly available information may also be accessible by children, for whom, some believe, this information may be confusing or corruptive (Robinson, 2013). A central challenge with the “community standard”, however, arises from its vague definition. While religious censorship is delineated by the teachings of the religion, community standards can be fluid and amorphous. This challenge of definition was famously framed

by Justice Potter Stewart in his 1964 opinion on pornography as “I know it when I see it” (Jacobellis, 1964).

National security is also frequently invoked as a justification for censorship. From this perspective, it is appropriate to limit the availability of certain information if this information may weaken national security protocols or provide adversaries with damaging information (Bohlen, 2013). The central difficulty of this perspective arises from the assessment of which information could pose a risk. Assessments can vary widely and are usually determined solely by the authorities who already possess the information. While restrictions due to national security concerns may be legitimate, authorities have also historically censored information because it was embarrassing or personally damaging.

Perspectives on censorship also differ based on culture and government. Numerous organizations assess freedom of speech around the world, including Freedom House and Reporters Without Borders, scoring countries based on the extent to which freedom of the press and free speech is enjoyed there. In discussion of the 2013 World Press Freedom Index, Reporters Without Borders secretary-general Christophe Deloire noted:

The Press Freedom Index published by Reporters Without Borders does not take direct account of the kind of political system but it is clear that democracies provide better protection for the freedom to produce and circulate accurate news and information than countries where human rights are flouted. (Reporters Without Borders, 2013)

Authoritarian regimes are routinely assessed as the most pervasive censors of information in the world, with China and Iran the most studied (Reporters Without Borders, 2013). Citizens often assume their own countries’ standards for censorship are common throughout the world, which can lead to misunderstanding, confusion, or anger if inflammatory material is shared in some countries but not others.

ACTIVISTS AND ORGANIZATIONS WORKING AGAINST CENSORSHIP

Numerous organizations around the world work to fight censorship, including Amnesty International, Campaign Against Censorship, Freedom House, Index on Censorship, and Reporters Without Borders. In the United States, key organizations fighting censorship include the American Library Association, Electronic Freedom Foundation, and the American Civil Liberties Union. The activities of these organizations vary widely, from advocacy and reporting to legal support and protest actions.

WikiLeaks, founded by Julian Assange, is one of the most influential organizations fighting censorship worldwide (Krotoski, 2011). The WikiLeaks Internet platform is designed to give whistleblowers a safe and anonymous platform through which to share censored information. Although there is some disagreement on the ethics of the WikiLeaks sharing process, the volunteer organization has continued to be influential over time.

Numerous artists are also prominent critics of censorship. Ai Weiwei has openly criticized the Chinese government for corruption and cover-ups related to human rights abuses and censorship of the press. He is involved in a campaign to release the names of all children killed in the May 12, 2008 Sichuan earthquake, despite the Chinese government's efforts to thwart volunteer investigators (Pickowicz, 2009). In Russia, Nadezhda Tolokonnikova and Maria Alekhina, members of the band Pussy Riot, were sent to prison (though subsequently released) for playing a song critical of the Russian state (Walsh & Watkins, 2014). Amnesty International, among other organizations, was heavily involved in a successful campaign to free both musicians (Amnesty International, 2013).

SOLUTIONS AND RECOMMENDATIONS

Censorship is a complex societal issue that will likely never be completely resolved. While cen-

sorship has a largely negative impact on society, legitimate concerns exist that necessitate some forms of censorship. Over time, the challenge for the global community will be to determine the types and extent of censorship that can be tolerated, along with those that may be moderated by the nature, context, and impact of the censorship itself.

As technology progresses, censorship by individuals will become increasingly difficult. Censorship by individuals has historically occurred through appeals to authorities over information rather than direct intimidation. As technology has advanced, many modes of information dissemination have developed, with information often shared through multiple modes simultaneously. The number of authorities controlling information, such as libraries, publishers, retailers, and webmasters, has expanded, while the scope of their control is shrinking. This means that individuals now must appeal to multiple authorities to prevent all access to certain information, and the disagreement of one point of authority subverts the entire effort. Thus, decentralization provides a natural limit to the ability of individuals to censor information. In addition, the growing availability of education for all people will increase resistance to censorship and reduce the motivation to censor information available to others.

Corporate censorship may be legitimately necessary for reasons such as limiting employee distractions, managing company communications, and protecting intellectual property. However, there is also a strong profit motive to limiting the sharing of information that may negatively impact the company, regardless of the ethical implications. For instance, the recent Sony Corporation hacking scandal uncovered significant gender-based pay discrepancies in the company, which ultimately cost the company millions of dollars (Shanahan & Goldstein, 2014). Other companies censor financial disclosures that may materially impact their business, quashing research indicating harm caused by their product, or not disclosing the theft of sensitive customer information. Although corporate censorship is primarily limited to information produced by the company itself, companies have more avenues to censor

information than individuals, including filtering content, limiting search results, and intimidating potential whistleblowers. Most societies have laws that protect some rights of workers and whistleblowers who expose unethical business practices, and sites such as WikiLeaks also support whistleblower protection. In addition, corporate integrity has become an increasingly important issue to consumers in recent years. Damage to corporate reputation arises not just from the leak itself, but also through company actions since the information was discovered, the steps being taken to resolve the issue, and through the company's actions toward whistleblowers. These trends toward openness and accountability should be encouraged by society and codified into law where appropriate. The absence of worldwide net neutrality is also a form of corporate censorship, as telecommunications companies stand to reap enormous benefits if they can control the information consumers access.

Censorship by governments is potentially the most far-reaching, restrictive, and dangerous. It is widely understood that some government censorship is necessary to protect security interests. However, censorship outside of national security interests can hamper research and development, damage international credibility, conceal human rights' abuses, and undermine the citizens' right to know about reasonable government activities. In addition, censorship has the potential to subvert the functioning of government, as those within the censored nation cannot assess programs and policy beyond the point at which the law is implemented. Because governments generate vast quantities of information, there is a tendency to broadly over-censor rather than invest the resources to precisely determine which information can and cannot be shared. Governments are also in the most powerful position to censor information through blocking, filters, and intimidation, and they typically possess the means and organization to engage in all such practices. Where possible, citizens should engage their lawmakers to ensure that government censorship is restricted as much as possible, and that

appropriate oversight is provided to those areas where censorship is necessary. Internationally, organizations such as the UN and its member states should continue taking steps to encourage other nations to increase open access to information and expand the freedom of their people.

FUTURE RESEARCH DIRECTIONS

In the future, research in censorship will be strongly guided by the growth of new communication technologies. For instance, recent research regarding Weibo and censorship or social media use in the Arab Spring uprisings suggest that a greater insight into the role of censorship on social media platforms is under way (Ng, 2013; Robertson, 2013). The growing use of information communication technologies by people worldwide will further enhance this research trend.

While much of the research will be centered on censorship of expression in the information age, larger international discussions will stimulate research regarding information access as a basic human right. Research investigating the agents of censorship and the necessary control of information offer unique possibilities for scholars to simultaneously look at both the history and future of censorship. Much of this discussion will be shaped by the American perspective on the freedom of speech, freedom of the press, and limitations on government information control as similar laws are frequently adopted worldwide.

Finally, historical censorship has centered heavily on the removal of cultural materials of developed societies during times of conflict. Research may be conducted that involves interviewing individuals leaving such areas and documenting knowledge of destroyed materials to prevent further loss and maintain a more consistent cultural record. For instance, the current conflict in Syria has led to the destruction of at least one UNESCO World Heritage site by the Islamic State (Stack, 2015).

CONCLUSION

Censorship has existed for as long as humans have shared information, and it is expected to continue for the foreseeable future. Development of information technologies, such as the printing press, telephone, and Internet, has added new capabilities for both freedom and censorship in society. Both the diversity of perspectives on censorship and further technological developments will surely make this topic even more complex in the future.

The importance of information freedom to the overall freedom of society is clear. Going forward, it is crucial that citizens of all nations continue to debate and address complex problems such as Internet access, government control of information, and international law as societies determine the acceptable limits and uses of censorship within, outside, and across national boundaries.

KEY TERMS AND DEFINITIONS

Censorship: The action or the use of authority to limit access to information that would otherwise be available in the public sphere. Censorship is often undertaken for concerns over morality, obscenity, blasphemy, or national security. It can be performed by individuals, groups, corporations, or governments and their agents.

Information Communication Technologies (ICT): Hardware, software, or network technologies that allow a user to create, edit, find, store, or share information. Examples include mobile phones, computers, intranets, social media platforms, telecommunications services, and the Internet.

IP Address: A set of numbers which specify a unique network address for a computer on a network.

Microblog: A blogging service focused on short entries, usually limited by a number of words or characters.

Net Neutrality: A concept of Internet governance stating that all network traffic should be handled without regard to content, source/destination, or interfacing equipment.

Wikileaks: A website designed to allow whistleblowers to anonymously submit information for distribution to the public.

Information-Based Revolution in Military Affairs

Rafal Kopec

Pedagogical University of Krakow, Poland

INTRODUCTION

Revolution in Military Affairs (RMA) is a general term describing a fundamental change in the character and conduct of armed conflicts. The majority of RMAs rely on the development of new technologies, however, they also include different aspects. RMAs typically consist of three elements: technological change, innovative operational concept, and organizational adaptation (Krepinevich, 1994). The RMA term was introduced by Michael Roberts in the context of revolutionizing the methods of waging war based on changes in tactics and technology between 1560 and 1660 (Roberts, 1956).

The subject of this article is the last RMA. The crux of it is to apply information technology (IT) in warfare. Being precise, the last RMA should be called Information-based Revolution in Military Affairs (Davis, 1996). However, the RMA term has been commonly attributed to Information-based Revolution in Military Affairs since the 90s. In 1993, Andy Marshall, the Pentagon's Director of Net Assessment, replaced the previous term "military-technical revolution" with "Revolution in Military Affairs" to underline a comprehensive change in military. It not only represents a technological change, but also a change in doctrine and organization (Watts, 2011).

BACKGROUND

Looking for the roots of RMA, it is necessary to recall a number of technological breakthroughs, whose synthesis provides the foundation of the

revolution. RMA – similarly to the majority of military revolutions in the history – it is not based on one groundbreaking innovation, but it takes advantage of a number of technological changes. In this case, the miniaturization of computer hardware and creation of highly efficient, decentralized data communication networks are the crucial technologies.

Applying these technologies in military was for the United States and others NATO countries the way to overcome the Warsaw Pact's quantitative dominance in conventional forces. A number of new types of weaponry were developed in the 80s, and they are generally divided into two groups: reconnaissance systems and striking systems (U.S. Congress, Office of Technology Assessment, 1986). The JSTARS (Joint Surveillance Target Attack Radar System) airborne reconnaissance system was the example of the first group, whereas the MGM-140 ATACMS (Army Tactical Missile System) surface-to-surface missile system represented the second one. These two elements were based on new technologies and cooperated closely thanks to highly-efficient data communication networks. They built together the innovative reconnaissance-attack system, and created background for further transformation.

The roots of RMA go to a given strategic problem, that is, anticipated confrontation with outnumbered Soviet forces. It is typical for military revolutions, which occur at a certain time and place just because they offer solutions to actual, not hypothetical, problem (Cohen, 2002; Bjerregaard, 2012).

The assumptions of the new concept were successfully tested during the Desert Storm operation

in 1991. Hence, RMA indicated the direction of transforming the American army, and afterward other modern forces. In simple terms, the transformation was aimed at converting armed forces into one coherent reconnaissance and striking system. It should be based on all available sensors and effectors connected with decentralized data networks (US Department of Defense, 2005).

REVOLUTION IN MILITARY AFFAIRS: ASSUMPTION AND PRACTICE

The Key Elements of RMA

The core of RMA consists of the following interpenetrated elements:

1. Computerization and Networking

Battlespace awareness would replace traditional determinants of dominance like firepower, survivability and mobility. Constantly updated knowledge about location of friendly and foe forces should become a critical factor which determines the military success. The quest for the information superiority has been the leading motive of military transformation. Implementing the new types of weapon is not considered as the essence of the revolution. The integration of all elements of battle formation with information distribution network is regarded here as the novelty. The C4IRS (Command, Control, Communications, Computers, Intelligence, Surveillance, Reconnaissance) system has become a critical component of modern armed forces. It is designated to the real-time coordination of the stimulus-response (from sensors to effectors) process. This *modus operandi* should overcome the eternal problem of warriors, which is uncertainty and opacity inherent in any military campaign, and should “lift” the Clausewitz’s “fog of war” (Owens, 2001).

RMAs are often linked to a broader change (Vickers, Martinage, 2004). Consequently, the

transformation driven by computerization and networking harmonizes with a wide-ranging social change toward an information society. The “Internet metaphor” is often recalled in each sphere (Shapiro, 1999). The background of RMA consists of elements typical for Internet: lack of central control over a system (creative anarchy), easy access to information from almost every place all over the world, and interconnectivity (peer-to-peer architecture) (Shapiro, 1999).

2. Smart Weapon (Precision-Guided Munitions)

It allows hitting the target with accuracy which was not accomplishable earlier. This capability implies the decrease in material requirements. Destroying an enemy object needs considerably less munitions compared to “dumb” munitions, but it requires precise information provided by “battle networks” (Watts, 2007). This trend corresponds with contemporary business, where information is the substitute of material and transport resources (Cebrowski & Garstka, 1998). Information dominance makes it possible to manage resources optimally.

3. Stand-Off

Increasing combat distance means the use of weapons can be launched far from the target. It makes a launcher invulnerable to enemy counter-measures. This kind of weapons is represented, for example, by cruise missiles used among others to carry out “punished” operation – the so-called Tomahawk diplomacy, which is a modern incarnation of gunboat diplomacy (Pretsch, 1999). A particular part of this trend is a widespread tendency towards robotisation (Doaré, Danet, 2014). The use of robots is more and more common not only in aviation (drones) and navy (first of all for minesweeping), but also on land. However, land is more demanding environment and projects of fully autonomous armed vehicles are still under development.

All these things may lead to make warfare resemble a computer game. Direct combat will be the exception rather than the rule as it increases the security level of own forces. Thus a stand-off operational model provides a means to carry out a military campaign despite the casualty aversion, typical for post-heroic Western societies.

RMA's Influence on Military

Deep transformation of leading (first of all American) armed forces is the effect of implementing the elements mentioned above. The crux of the transformation could be summarized as the list of the following oppositions:

1. Quantity vs. Quality

Since technological advantage is much more important than numerical superiority, the tendency toward decreasing the amount of armed forces is very clear. Modern technology replaces the potential expressed in simple numbers, that is, in the number of soldiers, tanks, guns or planes. It means that the tendency observed since the French Revolutionary Wars (the beginning of total wars) has been reversed. The quantity was the evidence of power in the past – the quantity of soldiers at first, then also the quantity of the essential types of weapon. Military power was determined by population power and economical power (e.g. heavy industry). Technological innovation was not a decisive factor, because it could be relatively simple assimilated by the enemy. The quantity was of crucial significance, which caused mass production of weapon and “mass production of men” (Howard, 1976, p. 121).

RMA has changed the situation significantly. The Gulf War in 1991 was a breakthrough moment. It positively examined the thesis about the significance of technology in modern warfare. Not only did the technology become a profoundly influential element of military campaigns, but it started to play a major role and to overshadow further elements.

2. Mass vs. Information

Mass – both in terms of quantity and “massiveness” of firepower and armor – is no longer the condition of military advantage. It has been superseded by fire precision and battleship awareness resulting from informational advantage (Blaker, 2006). According to Paul Wolfowitz, as warfare reflects the characteristics of the times, “we move from the Industrial Age with its emphasis on mass to Information Age warfare, which highlights the power of networked distributed forces and shared situational awareness” (US Department of Defense, 2005, p. 7).

The baseline of the advantage is to create armed forces based on the concept of network-centric warfare. Heavy armored units were declared an anachronism on the grounds of the belief that information replaces armor (Joint Vision 2010, 1996). A light military unit could avoid hits due to possession of complete information about an enemy. Multidimensional awareness and the ability to identify all forces in the battle space could build full-dimensional protection (Joint Vision 2010, 1996). When it comes to a single vehicle it could be possible because of so-called active protection systems (detecting an incoming bullet and using softkill or hardkill countermeasures). The eternal conflict of sword versus shield (or bullet versus armor as its modern interpretation) should be a thing of the past. The third element – information – has been announced the winner of this confrontation. As a result, the possibility to decisively defeat superior forces (when it comes both to the quantity and capability in traditional measures) by less numerous and “less capable,” but digitized and networked platforms will be achieved (US Department of Defense, 2005).

The huge project of the US Army's transformation – Future Combat Systems – was the appearance of that concept. Formally launched in 2003, it led to a new type of a brigade equipped with a manned and unmanned vehicle. Communication network was supposed to be a core of a brigade providing the connectivity and situational aware-

ness of every element of the unit. Heavy armor seemed to be redundant. Extensive information about an enemy's activity was thought to make it possible to build lighter combat vehicles (Future Combat Systems program was supposed to create "medium-weight" combat unit with 19-ton platforms transportable on the C-130 aircraft) (RAND Corporation, 2012). As a result, strategic mobility and capability to deploy troops in the theatre of operation should dramatically increase (Shinseki, 1999).

3. Riflemen vs. Sustainment Soldiers

In the information-based armed forces tending to avoid close combat due to stand-off capabilities, traditional soldier skills have ceased to be crucial. They have been reduced to the background and replaced by technological skills. The ability to operate technologically advanced equipment has become essential even for front-line soldiers, not to mention specialists like unmanned vehicle operators. As a result, the percentage of soldiers in the front line has been diminishing. This in turn has increased the role of broadly defined sustainment (soldiers, whose mission does not require direct contact with enemy). This tendency is derived from the assumption that network-centric units will be able to dramatically reduce or even eliminate the necessity for getting entangled in risky close-combat operations (Bingham, 2001).

4. Hierarchical Organizational Structure vs. Flat Organizational Structure

A flat interrelated organizational structure corresponds more closely to network-centric warfare requirements. Knowledge and consequently autonomy in decision making is going down the hierarchical ladder. Access to information on lower levels is less controlled, which entails more latitude in decision taking. A horizontal structure should involve such functions as fire, maneuver, transportation, and logistics (Blaker, 2006). This is the same process as in the business sphere – a

rigid organizational structure has been replaced by a more flexible network structure with a wide range of self-direction.

RMA in Contemporary Armed Conflicts

RMA-based armed forces were successful in the 1991 Gulf War and in the 2003 invasion of Iraq, however, experience with RMA is ambiguous. Insurgency phases of Afghan and Iraqi conflicts have verified the usefulness of the technology-driven military transformation in the conditions of the so-called asymmetric warfare. These conflicts highlighted the gaps between the claims to full-spectrum dominance and reality (Der Derian, 2009). The expectations that high-tech machines dominate the ground just like in the air and on the sea, where technological advantage almost directly results in strategic superiority, were not fulfilled (Kitfield, 2009). The outcomes of practical application of transformation have brought about a radical shift in the thinking of RMA. It has come a long way from enthusiasm to skepticism symbolized by entering the opposite concept of counter-revolution in military affairs.

The flagship project of RMA – Future Combat Systems – was limited and finally canceled (Krepinevich, Montgomery, 2009). The operations in Iraq and Afghanistan have undermined the RMA framework. Why such a radical change in attitude? Does it mean that the principles of RMA are invalid? I answer these questions by creating a few, not mutually exclusive, possible explanations.

1. The assumptions of RMA were unrealistic. They created a vision of changing the nature of war (not only the character of war) (Deptula, 2001). It involved the rejection of the Clausewitz's vision of war with its inherent unpredictability, thanks to the crucial importance of technology. Superior Information Position should become the key, if not the only factor determining the possibility to bring operation to a successful conclusion

(Alberts, Garstka, 1999). In effect, there are two fallacies from this approach: firstly, the absolute information superiority is possible; secondly, information could play a prominent role in conflict, in some ways substituting brute force.

The symbol of this approach was the concept of Effect-Based Operations. This approach was dependent on mathematical methods for predicting and measuring effects (Vego, 2006). The vision of future conflict as a one-sided undertaking was extremely chancy. This perception of conflict led to replacing strategy with technology as a crucial factor (victory as a simple consequence of technological advantage).

The vision of how to carry out military action was quite unrealistic and excessively technology-saturated. Contemporary armed conflicts show that Clausewitz's fog and friction cannot be ruled out (Seah, 2006) and the nature of war is still the same, despite the changes in equipment, organization, doctrine and military culture (Gray, 2005). Finally, the US Army abandoned the Effect-Based Operation concept, concluding that it assumes a level of unachievable predictability, is overengineered and discounts the human dimension of war (for example passion, imagination, willpower, and unpredictability) (Mattis, 2008).

Fantasies of high technology-driven military dominance repeat every once in a while. The Donald Rumsfeld's Department of Defense was dominated by technocrats similarly to the Robert McNamara's DoD at the time of Vietnam War (Guha, 2011). They both managed technologically sophisticated forces which were unable to decisively defeat far less advanced foes.

2. RMA as a legacy of the Cold War is irrelevant in the environment of contemporary armed conflicts including first of all counterinsurgency operations (COIN). Technologies developed in order to gain superiority in classic, high-intensity, state-to-state conflicts have appeared to be an "overinnovation." Such

technologies as aircrafts' stealth capability or counter-battery capabilities of modern (self-propelled and equipped with integral reconnaissance systems) artillery seem to be superfluous. They are expressions of the conventional orientation of military that engages the enemy directly (Tucker, 2006) while unconventional conflicts require rather an indirect approach, which is focused more on political and social solutions than on military tools (Freedman, 2006).

Light armor and protection based on information superiority have turned out to be a mistake in anti-rebel operations. Iraqi and Afghani operations have re-established traditional, non-information-based solutions. Heavy armored vehicles, including tanks, and Mine-Resistant Ambush Protected (MRAP) vehicles are still very usable. Paradoxically, MRAP vehicles are based on a simple but effective design with V-shaped hulls developed during the Rhodesian Bush War in the 70s. What is more, the sophisticated technology has not become the most desired resource, but the number of soldiers. The prospect of quick, "surgical" operations has not come to fruition. The direct physical presence of troops ("boots on the ground") in a conflict area is still valid. According to McGrath, the starting point of counterinsurgency operation should be to estimate a size of the forces in terms of troops to inhabitants ratio (McGrath historical analysis suggests a figure of about 13,26) (McGrath, 2006, p. 103). RMA has led to a paradoxical situation – in the past the army able to defeat regular forces was naturally numerous enough to occupy the terrain, but RMA-based forces are too small due to the pressure to reduce units.

RMA can be also perceived as a revolution distorted by politics. The demands to build new, lighter platforms were raised in order to adjust RMA principles to post-Cold War determinants (requirement of quick military interventions on a global scale related to the capability of global power projection). Platforms' "slimming" was not a part of core principles of RMA, but it

was justified in the spirit of RMA (information replacing heavy armor). Technological superiority should assert the American dominance round the globe allowing US forces to intervene almost immediately anywhere (Dalby, 2008). Its effect was a challenging program of Future Combat Systems that was based on controversial assumptions (combat platforms transportable on C-130).

3. RMA assumptions have not been fully realized because of the lack of technology. RMA-based transformation can be divided into two stages. The first stage, computerization, based on the implementation of miniaturized and highly-effective computer units in advanced types of weapons, has led to a gain in strike precision and stand-off launch capability. This stage might be recognized as relatively advanced one (Watts, 2011). However, the second stage, networking, responsible for making the battle space “transparent” and reaching indisputable information superiority is still immature.

RMA could be defined as the synergy between three elements: information acquisition, information processing and transfer, and the use of information in order to enhance firepower (in simple words: between sensors, connectors, and effectors). The first and the third elements are the strait extension of the reconnaissance-attack system concept, but the second element is crucial when it comes to real capabilities of RMA-based forces and the potential to cause a true revolutionary change. Sensors and effectors have been developed over decades, whereas the connection sphere relies on innovative technologies. However, their development is not as fast as it has been expected (one can compare ambitious objectives and a relatively slow progress of the Land Warrior program, that is, an integrated fighting system for infantry soldiers).

FUTURE RESEARCH DIRECTIONS

RMA has highly influenced the way technology advanced armed forces conduct military operations. This article signalizes major trends and significant controversies. However, there is a need to intensify research on particular issues and to focus on the following remarkable future directions:

1. The conflict of post-heroic Western mentality (symbolized by technology-driven trends allowing to avoid face-to-face confrontation) with heroic non-Western mentality (symbolized by suicide bombers called ultimate precision weapon) (Peters, 2009).
2. Do we deal with the limits of technological development in some areas, which poses a significant inhibitor of RMA-based transformation?
3. The issue that can be called “Dreadnought dilemma,” that is, building the Dreadnought battleship in 1907 (a faster, better armored battleship with more firepower than previous ones) re-established arms race between Great Britain and Germany and, consequently, undermined previous British advantage (Poundstone, 1993). So, implementing technologically advanced weapon can be perceived as a way to maintain advantage of a current leader, however, it also carries a risk of undermining this advantage.
4. Who is a leader in implementing a flat organizational structure: technology advanced armed forces or, paradoxically, decentralized, networked terrorism (Bousquet, 2009)?

CONCLUSION

RMA is an important step forward in the development of methods and means of warfare. Battle network systems like blue force tracking, which provides a common operation picture, offer sig-

nificant advantage over the enemy (Arkin, 2006). RMA should be perceived in that way: as a useful tool of waging war. However, the technology factor has been considered as something more. It has been claimed to be a decisive factor determining the outcome of every armed conflict (Maj, 2010).

Properly applied RMA can be the source of great advantage, in state-to-state and in counterinsurgency conflict as well. In fact, RMA is the continuation of an eternal pursuit, that is, to acquire more knowledge about the enemy than it could acquire about us. And so, the fundamental principles of war remain immutable, and the idea of changing the very nature of war has turned out to be an illusion.

KEY TERMS AND DEFINITIONS

Effect-Based Operations: The United States military concept for planning, executing and assessing operations to bring about particular enemy's behavioral effects by using the combination of military and non-military methods.

Future Combat Systems: The United States Army's modernization program that integrates manned and unmanned vehicles with decentralized data network. The program assumed creating a "medium-weight" brigade with increased strategic mobility thanks to using platforms transportable on the C-130 aircraft.

Information-Based Revolution in Military Affairs: The revolution in military affairs based on the application of information technology. It relies on the synergy between three elements: information acquisition, information processing and transfer, and the use of information in order to enhance firepower.

Network-Centric Warfare: The United States military doctrine assuming the possibility of transforming informative advantage (achieved by applying advanced information technology; first of all, connecting every element of a battle unit with decentralized data networks) into a full-spectrum dominance in the battle space.

Revolution in Military Affairs: A fundamental change in the character and conduct of armed conflicts. It typically consists of three elements: technological change, innovative operational concept, and organizational adaptation.

Smart Weapon: Munitions which allow hitting the target with high accuracy using a guidance system.

Stand-Off Weapon: Weapons launched at a long distance from the target to avoid defensive fire from the target area.

The Networked Effect of Children and Online Digital Technologies

INTRODUCTION

Given the ubiquity of technology and the changes it has undergone in terms of its multiple uses, meanings and effects in the later decades of the twentieth century, a growing attention started to be paid to social studies of science and social studies of technology (Goggin, 2006); and to technology (world of production, or what technology does to people) and the social (world of consumption, or what people do with technology), as part of a sociotechnical order (Matthewman, 2011).

As the society and technology context became more complex, thinking about the meaning and use of technology, especially when referring to children, entails reasoning about its effects, which sometimes are good and sometimes are bad. When unforeseen consequences occur, more questions are raised about technology. In this respect, the debates around politics cannot be ignored (e.g. Berg & Lie, 1995; Joerges, 1999; Latour, 2004; Winner, 1980) behind the design of technology, paradoxically encapsulating architectures of social control and domination (e.g. school, prison, hospital as institutions of modernity grounded in the principle of panopticism, see Foucault, 1979) that determine “human experience, behaviour and action” (Matthewman, 2011, p. 50). While at the same time it enables rich experiences, new freedoms, heightened pleasures of consumption, and new forms of public privacy (Matthewman,

2011, referring to Benjamin, 2004 dissertation about the Arcades of Paris project, a structure made of iron and glass he designated by the ‘human aquarium’).

Reactions against technological determinism¹, strongly suggested in the literature on perceptions of risk (see Anderson, 2006; Beck, 1992; Buckingham, 2009; Douglas & Wildavsky, 1982; Furedi, 1997; Giddens, 1990; MacKenzie & Wajcman, 1999), invited theorists to rethink technology in light of its social effects and on “explaining how social processes, actions and structures relate to technology” (Mackay & Gillespie, 1992, p. 685). Such theories are the social shaping of technology² (SST) and social construction of technology (SCOT). However, the interwoven relationship between online digital technologies and children’s everyday lives is far more complex than can be accounted for or reduced by technological or social determinisms (Bijker & Law, 1992; MacKenzie & Wajcman, 1999). Since both positions are equally flawed (Van Loon, 2002), a more cautioned position between contingency and control is proposed. Actor-network theory (ANT) appears as an alternative to the previous deterministic models. This model assumes a high degree of contingency foregrounding the role of technology in the construction of society (Matthewman, 2011), where “the power of things depends on how they are (as Latour says) ‘syntagmatically’ networked with other things, in competition with

paradigmatic counter-programmes of differently coupled actants. The power of things does not lie in themselves. It lies in their associations” (Joerges, 1999, p. 5). When referring to children, as Prout (2005) proposes, ANT solves the technology/society dualisms unresolved by the previous proposals and is a valuable possibility to understand the hybrid and interconnected phenomenon of childhood growing up in the context of the globalised, mobile and wireless late modern society. Ultimately, he finds in ANT a flexible epistemological possibility that can reach the ambiguity of contemporary life and the remarkable transformations brought by progress that have changed drastically childhood and children’s contemporary lives.

Corroborating Prout stand, the text develops from empirical examples that illustrate the embeddedness of online digital technologies within children’s everyday lives, in which one is transformed and transformative of the other (Holloway & Valentine, 2003), though neither “cannot be understood as either human or technical, as neither human nor technology controls the resulting patterns of relationships” (Bond, 2014, p. 62). Children’s accounts are presented here as part of a doctoral thesis guided by two objectives: to understand the personal values and meanings children might use to interpret their technologized lives; and to explore the various aspects enclosed in children’s heterogeneous and complex networked lives with the purpose of uncovering short and long term unintended harmful outcomes that may be (more or less) hidden in their digital experiences. This is a qualitative study that recognises children as competent ‘agents in their own right’ and is informed by a multi-lens approach drawing perspectives from the sociology of risk, childhood studies, socio-technical studies and zemiology in order to get a better understanding of children’s active choices and decisions in how they use the online digital technologies in their everyday lives.

Put simply, online and digital technologies frame children’s worlds and how children shape online digital technologies in their everyday lives.

In this scope, technologies and children are both agents in a relationship that implies more than an object/subject correlation. Technologies stress interactivity (between human and non-human materials), convergence (by implying the combination of different technologies – the object, the activity, and the knowledge), and agency (by stimulating and allowing the usage), while ‘enframing’³ and revealing their non-neutrality (Heidegger, 1977). Children, on the other hand, give subjectivity to technology in the way they use them to act in their own worlds and by how they relate to, with and through technologies (Heidegger, 1977; Matthewman, 2011), while affirming and confirming a modern mode of thought and being, as proclaimed by Heidegger (Van Loon, 2002).

BACKGROUND

The Actor-Network Theory: A Brief Contextualisation

In cultural and media studies one theory attracted attention, the Actor-Network Theory (ANT) (Goggin, 2006), a “conceptual frame for exploring collective sociotechnical processes” (Crawford, 2004, p. 1) and a conducive approach to benefit from a deeper understanding of the mutually constituting interaction, between technological affordances (Parchoma, 2014) and modern childhood (Prout, 2005) in the intersection of late modernity. Deriving from Bruno Latour’s, Michel Callon’s, and John Law’s work, the ANT method “draws on semiotics, social constructionism and symbolic interactionism, while being quite distinct from each of them in certain crucial respects” (Prout, 2005, p. 70). Despite its debilities and limitations – ANT is criticized for reducing the importance of human materials (Matthewman, 2011), it is argued that ANT offers a radical analytical method capable of opening the black-box of technology. Tracing its complex and heterogeneous relationships, reframing, engaging and intervening in familiar

issues using an unfamiliar perspective (Fenwick & Edwards, 2010), “while controversies are still ranging” (Matthewman, 2011, p.107).

This approach is particularly helpful in understanding shifting landscapes, like children and online digital technologies, since it avoids the distinction between ‘technical’ and ‘social’, replacing them by ‘actants’⁴ and ‘networks’⁵ (an actant is a network and vice-versa) enrolled in relationships of negotiation and translation (Neyland, 2006). And “[s]ociety, technology, and even agency, are network-effects” (Matthewman, 2011, p. 110) combining and exchanging competencies and exerting agency within the actor-network structure (Matthewman, 2011). The heterogeneous structure of ANT reclaims to technology the ontological materiality and agency previously replaced by stabilization and meaning in the SCOT model (Matthewman, 2011).

ANT examines social life through the relational associations between human and non-human entities (Prout, 1996), enrolled in a network and performing micro-interactions (e.g. social, economic, natural, educational) (Fenwick & Edwards, 2010). Human and non-human entities share the same ontology and agency within symmetric relationships, i.e. none has a privileged status over the other, and it is through these networked associations that all entities change and are changed by each other, since all (things, persons, knowledge, processes) are relational effects (Crawford, 2004; Fenwick & Edwards, 2010; Matthewman, 2011). In line with this, all entities confer significance, action, subjectivity, intention and essence to each other (designated as relational materiality) (Crawford, 2004). In short, ANT scrutinizes how the network is created, its associations and what holds the network together temporarily (e.g. resistances, negotiations, exclusions) (Fenwick & Edwards, 2010). Drawing from Foucault’s intellectual influence, ANT also envisages the materiality of politics and power affecting the position of actants in the network; and shares his definition of power as a strategy to affect action in a chain of human

and non-human entities (where, simultaneously, objects can act on subjects; and subjects can become objects) (Matthewman, 2011).

To deal with the ambiguity brought by the dissolving boundaries (e.g. public/private; agency/structure; inclusion/exclusion; adult/children) ANT discards the social dualisms that mark contemporary networked children’s experiences. The ANT model is a “more rigorous monistic strand” (Prout, 2005, p. 71) – a framework to understand the complexities that surround late modern childhood and the technological texts⁶ (Fenwick & Edwards, 2010), because things only have significance through their relationships within a collective (Matthewman, 2011).

Nevertheless, Star (1991) offering a criticism to ANT, contends that also those outside the network must be brought in to the analysis:

[...] we should consider the marginalized and the oppressed, those that do not get to design technologies, those that cannot access them, and those that, nonetheless, are compelled to feel their effects. Being outside the privileged network does not mean that you will be free of the effects of the technologies. (Star, 1991, cited in Matthewman, 2011, p. 121).

The network metaphor is a theory that describes – in Latour’s work description coincides with explanation – the social context as it arises from the connections between the actants through their activities⁷ (Mutzel, 2009). As Latour asserts, “[t]he meanings of artifacts are to be found in their use” (Matthewman, 2011, p. 71), which means that the social context does not arise a priori out of the networks; the social context is built from the networks and from the links that modify the actants, which means that nothing really exists outside the networked relations (Bajde, 2013; Latour, 1996). In line with this, ANT suggests that the relations between actants denote movement, displacement, transformation, enrolment and any contact and action is mediated:

[...] actants create the social by association and by translating one meaning into another – and therefore are always much more than ‘mere informants’. Analysts follow the actors and their constitution of categories instead of defining categories a priori. (Mutzel, 2009, p. 877).

Regarding the human-technology relation, the ANT model introduces the concept of affordances, proposed by Akrich and Latour. By affordances one understands “[w]hat a device allows or forbids from the actors – humans and nonhuman – that it anticipates; it is the morality of a setting both negative (what it prescribes) and positive (what it permits)” (Cited in Bloomfield et al., 2010, p. 416). For Latour (2002) the affordance is at the same time permission and promise in which the tool becomes an embodied experience, where technology fulfils more than a purpose, their mediation creates new possibilities, what the author calls being-as-another:

[...] thanks to the hammer, I become literally another man, a man who has become ‘other’, since from that point in time I pass through alterity, [...] This is why the theme of the tool as an ‘extension of the organ’ makes such little sense. Those who believe that tools are simple utensils have never held a hammer in their hand, have never allowed themselves to recognize the flux of possibilities that they are suddenly able to envisage. (Latour, 2002, p. 250).

Technologies also delegate and exhort morality, which means humans do not need to be present, as they can act on their behalf, displacing public morality to public interest to achieve changes in form and substance (Matthewman, 2011). An interesting example (see Christie, 2014) recently highlighted in the news, illustrates how through the panopticon principle technology may exert morality. The following example unfolds how human, non-human, knowledge and symbolic relations (Matthewman, 2011) work together to explain the public morality-interest movement.

A mother, tired of her son’s inability to answer her calls or texts (public morality – e.g. ‘answer the phone, it is important’), decided in association with an application developer, to create an application (named ‘Ignore no more’)⁸ that enables the deactivation of children’s mobile phone in case they don’t answer parents calls (morality role of technology), making it impossible to call or text anyone but the parents (public interest – e.g. ‘answer the phone, it is going to be deactivated’).

The affordance concept is compatible with the analytical tool for the social study of technology that later would be proposed by Ian Hutchby – inspired in Gibson’s work about ‘action possibilities’ – as a ‘third way’ to overcome the technological determinism/social constructionism impasse (Bloomfield et al., 2010; Matthewman, 2011). Hutchby (2001b) explains that different technologies have different affordances and to ignore this is to constrain technologies possibilities – in terms of meanings and uses. Affordances emerge during the interaction process between user and digital device (Still & Dark, 2013). To study the affordances of the tool, it may be a helpful methodology to develop a better insight of the properties (positive and negative affordances (Scarantino, 2003)) of different technologies and take advantage of this knowledge, in terms of avoiding unintended consequences and abuses (Conole & Dyke, 2004), that may arise from misinterpreting the technology.

Affordances can be designed⁹ and anticipated in order to enhance their detection (Xenakis & Arnellos, 2013) as pre-existent properties of the artefact (independent of users perception) or dependent of user’s experience or goals (Kannengiesser and Gero 2012, cited in Still & Dark, 2013). The designer invites users to behave (Withagen et al., 2012) and communicate meaning through the artefact (Xenakis & Arnellos, 2013). By the end of the process, the final consumer perceives (or not) the affordances and may also decide how he/she wants to give meaning to them (Hutchby, 2001b). In agreement with the users context, knowledge, personal needs and intentions, he/she redefines

affordances that were not found previously (e.g. as in the case of the telephone, PC or the Walkman). Hartson (2003, cited in Tsai & Ho, 2013) predicts four types of affordance in the design and evaluation process: cognitive, physical, sensory and functional:

[...] cognitive affordance is design feature that helps users in knowing something; physical affordance is design feature that helps users in doing a physical action in the interface; sensory affordance is design feature that helps users sense something such as seeing or hearing, and functional affordance is design feature that helps users accomplish work. (Tsai & Ho, 2013, pp. 1250-1251)

Tsai and Ho (2013) explored how design affordance may affect smartphone usage and explain how the four types of affordance considered in the design process apply in the design-device and inferential-user interaction:

The label font size in the icon of icon [sic] on smartphone screen is large enough to read easily is an example of sensory affordances. In comparison with other three types of affordances, the functional affordance is a higher-level affordance and it could be seen as the usefulness of a system function. For instance, the process of accomplishing screen unlocking (functional affordance) on iPhone 4 might be decomposed into three stages – seeing the arrowhead displayed on the screen (sensory affordance), understanding on the meaning of arrowhead (cognitive affordance) and swiping the arrowhead touch panel (physical affordance). (Tsai & Ho, 2013, p. 1251).

A BRIEF EXPLANATION ABOUT METHODOLOGY AND ETHICS

This text builds from selected data collected using a qualitative approach informed by the constructivist tradition (Guba & Lincoln, 1998). Participatory

strategies were privileged to generate in-depth narrative data with school-aged children from diverse socio-economic backgrounds and from younger ages in line with gaps identified in the literature (Livingstone & Bulger, 2013). A total of 41 participants aged mainly between 10 and 12 years old were enrolled in this participatory research.

The ethical framework that guided this study endorsed the consequentialist model elaborated from the feminist ethic of care (Denzin & Lincoln, 1994) and ethical symmetry (Christensen & Prout, 2002). To protect children's rights to privacy and confidentiality, identities and personal information about the participants were concealed. Respondents' identities were replaced by a pseudonym.

Dialogical, flexible, reflexive techniques supporting participation and power balance were privileged with the aim of grasping the subjectivities, complexities and contradictions inherent to children's digital lives and giving children the opportunity to express their knowledge, share experiences and reflect on everyday situations. In line with this, group activities (e.g. games, drawing and role playing games), focus groups, group and individual interviews and participant observation were the techniques applied to stimulate discussion about a topic, to observe the participants' behaviour, routines and events occurring in their everyday contexts, offering interesting insights about their digital habits and interactions. During the research meetings children were invited to express their opinions, share their experiences and reflect on situations that emerge within the context of their digital and online lives. With the purpose of gaining a rich interpretation and reflexivity across the true purport of children's understandings, feelings and experiences, two methods, including thematic and narrative analysis, were applied to scrutinise and organise the data.

To solve the quality issue from a social-constructivist research standpoint and ensure the quality of the analytical generalizations (Yin, 2010), triangulation was applied by combining

different techniques for data collection: inter-methods triangulation, triangulation of data, and theoretical triangulation.

RESULTS AND DISCUSSION

Children's relationship *to, with and through* technology (Heidegger, 1977; Matthewman, 2011), *how they use and what they use it for* (Buckingham, 2006), is changing and challenging both adults' expectations about childhood, as well as children's everyday experiences (Bond, 2014). New forms of sociality (Matthewman, 2011), the dynamic construction of the self (Giddens, 1991), and new meanings and cultures of use (du Gay et al., 1997) are outcomes that nourish and are nourished by post-modernity corollaries – anxiety, insecurity, uncertainty and ambivalence (Ekberg, 2007) and are heightened by complex and complicated relationships and interdependencies where children, family, society, and digital online technologies are network-effects exerting agency within a complex actor-network structure (Latour, 1996; Matthewman, 2011; Prout, 2005).

Due to the changes and challenges that ubiquitous communication technologies brought to social dynamics, the boundaries between positive and negative experiences are often blurred, so one has to rely more on ambiguity than on certainty. In accordance with this matrix, data analysis demonstrates how a complex network of human and technical agents is challenging children's meaningful use of their participation rights online, reconfiguring the landscape of childhood, contributing to the magnification of old problems and the creation of new forms of vulnerability (Yar, 2012).

Upholding boyd's argument (2014) the way social media are designed challenges private/public and security/insecurity boundaries and encourages certain practices. On the one hand, challenge children's control when "balancing privacy and safety" (boyd, 2014, p. 47) and, on the other hand, afford children's online participation to

reach a broader, (un)known and (in)visible audience while, simultaneously, by default make them more easily searchable by such audience – often inaccurate with the one imagined by the children. During the fieldwork some participants reported concerning about their privacy and safety online. However, field impressions suggest that does not mean they are actually taking advantage of private settings, because they simply "don't know how to do that" (Grace, aged 12) and, to complicate matters, at least in the case of the Facebook, privacy settings are complex and constantly changing (boyd, 2014). When asked if they would publish a picture of themselves in a public space, all participants responded with a peremptory "no" as an interesting excerpt, depicted from one of the groups, reveals.

All participants in unison: No.

Grace [aged 12]: Everyone would see us. [...] 'Hey how embarrassing.' [She laughs] (PG4_251013)

Nevertheless, some children took real interest in changing their social profiles setting, making them more private, protected and secure. Participants seem to also be aware that a wider public can observe what they publish on the social networks. As Figaro clarifies Facebook is "always public" and "everyone can see" (PG1_270114) and "all the world can know", Tinker Bell adds (PG2_280114). Nonetheless, and despite their parents' anxieties, some children reported accepting friend requests from strangers, which according to them is not 'a big deal' as long as they do not talk to them.

Alana [aged 12]: I add [strangers], but I don't... [Interrupted]

Figaro [aged 12]: [Finishes Alana's sentence] But she never chats with them¹⁰ [...] (PG1_111113)

As Figaro afterwards explains, "It's just to have friends on Facebook" (PG1_211013). This seems to be reason enough to overlook some

precautions, such as for instance privacy settings regarding their personal pictures, making it possible for the wider public to lurk in, disregarding that their photographs can be downloaded and distributed. Children seem to adopt a ‘nothing happens to me’ attitude that confers them an illusory sense of control.

Moreover, other digital devices and online platforms, such as Ask.fm, Facebook and Stardoll were often part of children’s narratives, the scenario where gossip, rumours, rudeness, pranks, abusive requests and abuse of trust may occur in the fluidity of their on/offline interactions. Taking advantage of its main feature – anonymity, Ask.fm enables users to sometimes interact in a harmful/abusive fashion as the following participants’ accounts depict. Tinker Bell talks about a girl friend who published a comment saying that she cut herself (not on purpose) and how “everybody sent messages saying: ‘kill yourself’, ‘cut yourself’ ‘die’” (PG2_040214). And Grace, Rose and Maggie address the case of a young and well-known Portuguese actress who was targeted by rude comments on Ask.fm. In this situation, it is noteworthy how Maggie censures people’s character while Grace blames social software affordances, exemplifying the double-sword of modernity (Giddens, 1990). Maggie and Grace empathise with the young actress episode, because when this happens to them they feel sad and “everyone sees it” (PG4_251013).

Rose [aged 11]: *She took a picture. And a boy said: ‘If I were you, I would take forty pills and die’.*

Grace [aged 12]: *Ah, you know why? She has little breasts and people tease with her: ‘Hey, when will your boobs grow?’ She is 16 years old. ‘And your boobs? Are they hidden in your ass?’ People always say that, on Ask. That thing you ask questions.*

[...]

Researcher: *Do you think that people would have the courage to say that in people’s faces?*

Maggie [aged 12]: *They are cowards.*

Grace [aged 12]: *[...] do you know why? Because they can say it in private. (PG4_251013)*

Ask.fm and Facebook are platforms where rumours and gossip start and spread very quickly as the girls’ accounts below reveal. Giselle sent emoticons with little hearts to Kiara using a boy’s Facebook profile to which Kiara responded. The plot was set for what was to follow. Despite not having an account on Ask.fm, Kiara suffered from gossip and questions on the social network through Tinker Bell’s account, validating Star’s (1991) argument that even the ones outside the network are constrained by its effects.

Tinker Bell [aged 11]: *Two people from the school and two people on Ask came to me to tell me that I gave a kiss to [name of the boy]. And I gave him no kiss. Then, they said that [...] [name of the boy] had S-E-X with Kiara.*

[...]

Tinker Bell [aged 11]: *And the questions appear on my Ask. [Name of a girl] also received it.*

[...]

Tinker Bell [aged 11]: *They told they were a couple because Giselle sent little hearts to Kiara from [name of the boy]’s Facebook. And she replied: ‘You’re always in my heart.’ And someone must have read it in the Library and came to ask questions, to Ask.fm, ‘How long are they are sweethearts?’ And so. (PG2_180214)*

Taking advantage of SNS audiences, rumours published and republished on the Facebook can circulate largely to the point where no one can trace the source of the story (Best & Bogle, 2014). Nevertheless, the stories circulate as real, and to authenticate the evidence they tend to be localized in terms of space (nearby) and time (recently) while they also carry the message that the world is a dangerous place (Best & Bogle, 2014). During a meeting, participants were talking about a

paedophile that was supposedly acting ‘nearby’. According to Tinker Bell, a friend of hers published the alert on the Facebook and shared it on Tinker Bell’s wall.

Tinker Bell [aged 11]: *I don’t know if I told you that this girl posted twice on Facebook saying that a paedophile was in the neighbourhood.*

[...]

Tinker Bell [aged 11]: *She asked me for permission to put it on my Facebook too. I told her ‘Yes’. There’s nothing wrong about that.*

Giselle [aged 10]: *Have they already caught the paedophile of [locality]?*

Tinker Bell [aged 11]: *I don’t know. I never heard of him again. (PG2_261113)*

Also the source of the alert makes the story believable as several others corroborate the story. Weeks later, during a meeting, Tinker Bell announces that the paedophile was caught by the police. When asked if she saw it in the news, once again the story develops untraceable.

Tinker Bell [aged 11]: *They [police] already caught the paedophiles of [locality].*

Researcher: *Yes?*

Tinker Bell [aged 11]: *They caught one. It was in the newspaper.*

Researcher: *But have you seen the newspaper?*

Tinker Bell [aged 11]: *No, a friend of mine told me. Her godmother lives there too. (PG2_140114)*

Children regard digital and online worlds as just another setting where they manage their daily lives and relationships surpassing the dichotomy off/online, because they are not different or separate, but constitutive (Holloway & Valentine, 2003). In this sense, children’s everyday social relationships and activities are embedded within an off/online continuum.

Online social communities are popular among the participants, and many of their daily interactions happen within these platforms. However,

they are sometimes used to play pranks or being uncivil.

Excerpt A

Tinker Bell [aged 11]: *Ah in Stardoll I’m always blocking people, but that’s also because I want to.*

Researcher: *Because you are playful?*

Tinker Bell [aged 11]: *But not with my doll, I do it with another one I only created to annoy people.*

Researcher: *But on Stardoll, you can block and unblock [people]?*

Tinker Bell [aged 11]: *Yes.*

[...]

Kiara [aged 10]: *That is to make fun of people, you know? Because she... [interrupted]*

Tinker Bell [aged 11]: *Because she [talking about Giselle] creates dolls to tease Kiara.*

Researcher: *Who?*

Tinker Bell [aged 11]: *Giselle. She creates guys who are always nagging Kiara like this: ‘Do you want to date me? Do you want to date me? Do you want to date me?’*

Kiara [aged 10]: *‘Do you want to date me, you crooked teeth?’*

Tinker Bell [aged 11]: *‘You are ugly with crooked teeth, but I want to date you.’ It’s so cool to irritate people. It is better not to say this but [pause]. I like to call Kiara bad names. Silly, stupid, fool, sucker. Kiara talks to me: ‘Hello stupid.’ and I say: ‘Hello.’ And she says: ‘Shut up stupid.’ And I say, ‘I have not even talked’, and then she begins: ‘Shut up stupid.’*

Researcher: *Do you get sad when she says that? Never ever? In any day, any time?*

[She nods to me negatively]

Tinker Bell [aged 11]: *Ah. When she calls me bad names very [pause]. As once she called to [name of a girl], unintentionally. She called her a bitch. And [name of a girl] got very upset with her. (PG2_121113)*

Excerpt B

Tinker Bell tells me she has several dolls (Stardoll). One of them has her name, and when people ask for her name she doesn't lie, because, ultimately, they 'don't know if it's my true name or not'. And then she adds, 'I have three dolls. One of them is 'Evilllllll', with eight L's'. She uses this doll with 'ugly hair' when she wants to mistreat someone, because in her own words, it's 'fun'. She says: 'I call someone ugly, but I don't know if the person is really ugly, it's just for fun'. After explaining that 'when someone mistreats you, you can block and report' (or when people ask 'where are you from'), she also explains that she has 'fake' dolls, because if someone reports her, she is banned from the game. Having more than one doll is a strategy to do bad things without running the risk of being banned with the dolls they use to effectively play the game. And she adds, 'when I see someone mistreating a person, I stay quiet in a corner'. I got curious and asked her why she did that. She answered it was to avoid being banned. Tinker Bell and Kiara often play the game and mingle together in the game, where they sometimes simulate to mistreat each other just for fun. (Researcher's Field report PG2_221013)

The conversations above uphold Vandebosch and van Cleemput's (2008) argument that these practices are not intended to cause negative feelings or hurt someone. As Tinker Bell reinforces at the end of the first transcript it is *unintentional*. In their own words it is meant to be *fun*, "a sign of common understanding, or a kind of playful interaction between friends" (Vandebosch & van Cleemput, 2008, p. 501), nevertheless, despite common such practices may be interpreted differently by adults moral values, in particular, parents. In one exchange of text messages between the two girls, Kiara by accident sent the text messages to her mother and got punished because of the content (GP2_040214), which illustrates how children and adults have different perceptions of what is acceptable or not acceptable.

Taking advantage of mobile phone tariffs affording free voice and text communications, as well as anonymity, participants sometimes use this medium to insult each other. In the following situation Giselle is harassed by a girl via text message and, afterwards, by voice call. In the episode is noteworthy how the group got involved and how the situation loses significance when Giselle realizes that the stranger is in fact a girl with special educational needs from her class. This episode, despite being an isolated case, may indicate a new direction in research on bullying involving children with special educational needs and the use of online digital technologies that needs to be addressed and further investigated. The following event portrayed below reveals how online digital technologies empowered the girl with special needs to take an active and hostile role that challenges the taken for granted image of this group depicted as victims.

Kiara [aged 10]: Call her.

[...]

Giselle [aged 10]: Ya. I'll call her to see if I know the voice.

Tinker Bell [aged 11]: It's free to call her.

[...]

[The phone rings]

Giselle [aged 10]: Hello.

Girl X: Hello.

Giselle [aged 10]: Who is this?

Girl X: Clown.

Giselle [aged 10]: Who is this?

Girl X: [laughs] Stupid.

Giselle [aged 10]: Tell me your first name.

Girl X: [laughs] Geek.

Tinker Bell [aged 11]: It's [name of a girl] [whispering].

Giselle [aged 10]: I have her phone number [whispering].

Jenny [aged 10]: Call ended [whispering].

Giselle [aged 10]: Call terminated? I'll insist again.

[...]

[Girl X answers the phone again]

Girl X: What do you want, clown?
Giselle [aged 10]: Is that you Girl X?
Girl X: Clown.
Giselle [aged 10]: Piiiiiii.
Girl X: [laughs] Geek.
Giselle [aged 10]: Do you know me?
Giselle [aged 10] and Mary [aged 12] in unison:
Call ended. [Both girls Laugh]
Mary [aged 12]: Try again.
 [...]
[Girl X rejects the call]
 [...]
Tinker Bell [aged 11]: I also do this with Kiara.
Kiara [aged 10]: That's right. And I do it with her.
Giselle [aged 10]: Dumb.
Researcher: This?
Tinker Bell [aged 11] and Kiara [aged 10] in unison: Yes.
Researcher: Seriously?
Kiara [aged 10]: Hum hum.
Researcher: Why?
Tinker Bell [aged 11]: Unknown number. I call her and pretend I'm someone else.
Kiara [aged 10]: Ya.
Researcher: Why?
 [...]
Tinker Bell [aged 11]: It's funny.
Researcher: It's funny?
Tinker Bell [aged 11]: Yes.
Kiara [aged 10]: Hum hum.
Tinker Bell [aged 11]: But when we send messages, it has her name and has my name.
[Both girls laugh]
 [...]
Researcher: What are you going to do about this?
Giselle [aged 10]: I don't know. If it's a friend of mine, I'll do nothing.
 [...]

(GP2_140214)

CONCLUSION

The combination of childhood and technologies serves as a powerful focus for debates (not new in

the media field) that have been struggling between renewed hopes and fears, and risks and opportunities, where digital and online technologies are responsible for liberating and empowering versus destructing and betraying the essence of childhood. Clearly, as unsupervised personal, online and mobile technology becomes more entrenched in children's lives more complex are the challenges to face. And though most of children's digital and online experiences are positive, evidence suggests that children can easily engage in ambivalent interactions and decisions.

Nevertheless, this embeddedness of technologies in children's quotidian has to be understood in light of other macro, micro and meso societal changes that need further attention as these affect the social reality of families and consequently children's everyday lives. Conforming with this, the narratives included in this text provide the unsettling context adjoining the social processes arising within the scope of late modernity, enhancing tensions (e.g. agency-structure, public-private) that impact on social representations of childhood and through which children become visible or invisible; and the rationales that may shed further light on the extent to which the digital realm is embedded in children's everyday lives through heterogeneous and complex networks that link together human and non-human entities in which "children's social worlds are formed, not just through their associations with other children, but also through their association with their material surroundings" (Valentine & Holloway 2002, p. 317).

Drawing from everyday situations, children's voices were privileged as the main source of understanding to inform a multi-lens approach drawing perspectives from the sociology of risk, childhood studies, socio-technical studies and zemiology. In particular, this study benefit from a conducive approach, the Actor-Network Theory, as a conceptual framework to gain a enriching understanding of the mutually constituting interaction between technological affordances and modern childhood, arising from the intersection of late modernity. Considering the rapid pace of

technological innovation and how children (re) adapt to its fast pace, creatively interpret technological affordances and (re)construct media trends, the fieldwork follows a research with children approach in which children were encouraged to reflect and share their understanding vis-à-vis their technologized quotidian. Considering participants' accounts, interpersonal relationships can indeed become sour when the technology is misinterpreted, as it is suggested, demonstrating how heterogeneous and complex networks influence human action and relationships.

In summary, ANT avoids technological and social reductionisms/determinisms, since what entities do when they meet is unpredictable (see Latour key example, "[t]he key does not act by itself, but is also acted upon by other entities linked in the network" (Fenwick & Edwards, 2010, p. 10)) meaning that,

Social life cannot, therefore, be reduced either to the 'purely' human or to the 'purely' technological (or animal, vegetable, mineral, abstract...). Neither the human nor the technological determines the overall patterning or ordering that results from their combination. (Prout, 2005, p. 70-71)

According to Prout (2005), with ANT new forms of childhood arise as a result of complex and heterogeneous network connections established between children and technologies. Artefacts influence human actions, intentions, meanings, relationships, routines, memories, perceptions of the self; and ideas, desires, meanings and actions influence the artefacts. Drawing from a school playground as an example, Fenwick and Edwards (2010) note that non-human materials (playground) when combined with human entities (children) "produce particular activities, speech, social groupings and exclusions, injuries, even gender identities" [...] [that] exclude, invite and regulate particular forms of participations. And such social practices can determine meaning by reinforcing the political effects of technology. As Moinian states, "we can neither simply blame nor

celebrate these new media and their impact on our conceptions of childhood without understanding their complexity and their potential contradictions" (2006, p. 51, paraphrasing Buckingham, 2000).

FUTURE RESEARCH DIRECTIONS

The examples included in this text offer a small fragment of knowledge, centred on specific problems and situations. However, these are extremely helpful to reach the subjectivity, the delicacy and complexity of matters and meanings children bring to their online experiences and to understand the networked complexities enclosed in the embedded relationship between children and online digital technologies in the context of late modernity. Children's accounts reflect the heterogeneity, the complexities and the context of late modernity and life itself with "new capacities to act and hence new fields of power" (Prout, 2005, p. 115) that create new possibilities and problems in need of ongoing research.

KEY TERMS AND DEFINITIONS

Actor-Network Theory: Social life understood through a network where human and technological entities have agency to interact and transform each other within symmetric relationships.

Children: The term 'children' follows the United Nations Convention on the Rights of the Child (UNCRC) definition as those under 18 years.

Network: Network is a concept employed to suggest flow and connection among the heterogeneous human and technical entities.

Online Digital Technologies: Refers to devices and services connected to the internet that afford flexible communication and connectivity for the user. Nevertheless, sometimes the conjunction 'and' is used between 'online' and 'digital' to include the reference to devices or experiences that do not afford or imply a connection to the internet.

Social Construction of Technology: Technology understood as a social phenomenon embodied in complex social processes.

Social Determinism: The notion that society shapes technology.

Social Shaping of Technology: Technology understood as a social product.

Technological Affordances: The possibilities and permissions that a technological artefact encloses. These possibilities and permissions emerge during the interaction process between user and the technological artefact.

Technological Determinism: The notion that technology shapes society.

ENDNOTES

- ¹ “Technological determinism is the notion that technological development is autonomous with respect to society; it shapes society, but is not reciprocally influenced. Rather, it exists outside society, but at the same time influences social change.” (Mackay & Gillespie, 1992, p. 686).
- ² The SST “is seen as playing a positive role in integrating natural and social science concerns; in offering a greater understanding of the relationship between scientific excellence, technological innovation and economic and social well-being; and in broadening the policy agenda, for example, in the promotion and management of technological change” (Williams & Edge, 1996, p. 545).
- ³ The word ‘enframing’ is used by Heidegger (1977) “to describe modern technology’s way of revealing the world as standing-reserve” (Matthewman, 2011, p. 14).
- ⁴ An actant is an actor with agency after being translated and becoming part of the network. However, it is not helpful to distinguish between them once ‘actant’ is not much used in ANT analysis (Latour, 1991). For the sake of clarity, the concept ‘actant’ will be used instead of ‘actor’, to avoid being misinterpreted with ‘actor’ suggesting human agency (Matthewman, 2011).
- ⁵ Referring Latour’s and Woolgar’s work, Fenwick and Edwards state that “[i]n ANT’s early years, the term network was employed to suggest both flow and clear points of connection among the heterogeneous entities that became assembled to perform particular practices and processes” (2010, p. 15). However, with the advent of technological networked systems, the network metaphor became problematic.
- ⁶ Hutchby refers to Grint and Woolgar work to explain what ‘texts’ are. “[T]echnologies should be treated as ‘texts’ that are ‘written’ (i.e. configured) in certain ways by their developers, producers and marketers, and have to be ‘read’ (i.e. interpreted) by their users or consumers” (Hutchby, 2001, p. 445).

Suggestions for Communication of Information for Multicultural Co-Existence

S

Noriko Kurata

Tokyo University of Science, Suwa, Japan

INTRODUCTION

Given the advancement of globalization today, an increasing number of people are emigrating from the country they were born in or from the country where people of their same ethnicity live, to other countries seeking economic affluence and a safe and secure life. Even in Japan, a country that is surrounded by sea, the number of resident foreigners is increasing every year. In any country and in any region, it is difficult to stop globalization. Local governments all over the world are facing the common challenge of fostering mutual understanding among existing local residents and people with multicultural backgrounds or multi-culture residents (MCR), rather than excluding them, and encouraging mutual acceptance.

In Japan, Japanese residents (JR) and MCR are frequently experiencing each other's culture through local events such as cooking classes and gymnastics exercises. Local governments have established many places for such experience-based cultural exchange. However, culture includes things that can only be expressed through language. These are ordinances. Ordinances are the norms of the region that regulate the rights and duties of the residents. If one does not understand the language accurately one cannot interpret the ordinances. Even for those people who cannot interpret ordinances correctly, if they violate an ordinance it is punishable by fine. Persons who do not know about an ordinance suffer disadvantages due to their ignorance. Ordinances are a part of the local culture that should be known to those who intend to live in the region.

As a means of knowing the local culture, there are ways of finding information related to local governments by searching on the website. Most information about local governments in Japan is distributed in Japanese, but through the introduction of machine translation, it is possible to convert it into a language that users themselves find easy to understand.

In this chapter, the examinations on the trend towards an increase in MCRs in Japan were made first, and examples of introduction of machine translation in Japan were also presented. Further, the results of surveys were described as status of communication of information in Japan's basic local governments, some issues were extracted, and available countermeasures were proposed.

BACKGROUND

Increase in Resident Foreigners in Japan

As shown in Figure 1, resident foreigners in Japan are increasing every year. According to the population census (Ministry of Internal Affairs and Communications, 1995; 2000; 2005; 2010; 2015), resident foreigners numbered about 1,140,000 in 1995, but have increased to more than 3,130,000 in 2015, increasing to more than double in 20 years. The composition ratio of resident foreigners in the total population of Japan in 1995 was about 0.9% but it was about 2.5% in 2015, increasing to nearly three times.

Figure 1. Trend of Resident Foreigners in Japan (Tabulated by the author based on “Population census”, Ministry of Internal Affairs and Communications)

Figure 2 is based on December 2015 statistics on resident foreigners (Ministry of Justice, 2015). The language used by the resident foreigners is shown. Thirty countries from where there are a

large number of resident foreigners were extracted from this data and the calculation presents a total of the national languages and official languages used in these countries. Although Chinese-language

Figure 2. Languages Used by Resident Foreigners in Japan (Based on “Statistics on Resident Foreigners”, Ministry of Justice; tabulated by the author based on the languages of the top 30 countries from where there are a large number of resident foreigners)

users occupy more than 30% of the total, one can observe that users of a variety of languages reside in Japan.

This not only shows that there are diverse languages but also shows that there are people with various cultural backgrounds residing in Japan.

In the “Field Study Related to the Resident Foreigners’ Awareness of the Japanese Language” conducted by the Agency for Cultural Affairs (2001) targeting 600 foreigners residing in Japan, 10 questions were asked related to problematic situations and unpleasant situations arising due to lack of proficiency in Japanese-language conversation, reading and writing (multiple answers allowed). As a result, the maximum percentage was for “hospitals” at 21.3%, followed by “relations with neighbors” coming second at 17.0%, “workplace” being third at 15.1%, and “City Hall Office” being fourth at 11.5%. Difficulties were experienced in daily life and at the City Hall where explanations about the public system are received.

The above survey also examined Japanese-language proficiency. Regarding listening abilities, 21.0% answered “can understand well”, and regarding speaking skills, 17.4% answered “can speak well”. About reading abilities, 84.3% could read hiragana, 75.2% could read katakana, 51.5% could read romaji, 48.5% could read kanji a little, and 19.6% could read kanji and also understand the meaning.

Further, in the above survey, when asked whether they consciously learn Japanese in some way, about 90% (89.7%) answered “learning”. Those who were “learning” were asked eight questions about the method of learning, the most number

of responses was “at a Japanese-language class in the municipality” at 59.9%. People who attended Japanese-language classes were asked 12 questions about how they wanted to utilize the results of their learning at the Japanese-language classes (multiple answers allowed). Table 1 shows the top answers with high selectivity. These results show that resident foreigners have a high consciousness of wanting to know the culture of Japan through the Japanese language.

MACHINE TRANSLATION

Technological Progress

Automatic translation by machines is being researched as an aid to enable humans to understand multiple languages. It is a technology called machine translation (MT) or automatic translation. MT refers to the translation of text in one language (the source language) to another language (the target language), using software.

The methods of MT include the rule-based method in which experts write the translation rules and translation based on the paginal translation method. Translation based on paginal translation can be broadly classified into example-based machine translation (EBMT) and statistical machine translation (SMT). (Sumida, 2009)

The rule-based method can lead to a highly precise translation when there is compliance, but as making grammar rules for minor languages is difficult, it takes a huge amount of time for multi-lingualization.

Table 1. How would you like to utilize the results of learning at Japanese-language classes?

Order	Utilization of Content	Ratio (%)
1	Speaking Japanese	71.7
2	Learning about daily life and culture	54.2
3	Increasing the number of friends	47.7
4	Talking to people (finding a conversation partner)	43.7
5	Deepening understanding about different values (different cultures) from one's own	30.8

EBMT searches for similar parallel translation data from previously stored bilingual translation data, and conducts translation by revising this. (Kurohashi, 2009)

SMT extracts the model required for translation from the bilingual data and translates by maximizing the probability based on this. (Tsumamoto, 2009).

Research on SMT is increasing in accuracy in recent years, due to techniques of automatic evaluation of translation results.

Case Studies of Introduction of Machine Translation in Japan

In private translation systems, translation sites such as @nifty translation or Yahoo! Translation use the rule-based method and translation sites such as Google Translate and Bing Translator use the SMT method.

The Japan Patent Office has adopted SMT and in order to enhance the accuracy of MT of patent literature, they have provided a Japanese-English Machine Translation dictionary from 1999, and a Chinese-Japanese Machine Translation dictionary from 2012, on the web. (Japan Patent Office, 2015)

At The Ministry of Justice the “Japanese Law Translation Database System” was developed from 2009, offering the translation guide, “The Standard Legal Terms Dictionary”. In this database system, the following disclaimers are displayed:

This system is operated by the Ministry of Justice and is a website that provides translations of Japanese laws and regulations. All translations contained on the Japanese Law Translation Database System are unofficial. Only the original Japanese texts of the laws and regulations have legal effect, and the translations are to be used solely as reference materials to aid in the understanding of Japanese laws and regulations. The government of Japan is not responsible for the accuracy, reliability or currency of the legislative material provided in this website, or for any

consequence resulting from use of the information in this website. For all purposes of interpreting and applying law to any legal issue or dispute, users should consult the original Japanese texts published in the Official Gazette. (Ministry of Justice, 2009)

Evidence based on laws in the Japanese language is required for legal problems such as lawsuits. Rather than litigations, the information published here is sufficient if one wants to gain a rough understanding of rights and obligations in daily life.

CHALLENGES AND COMMUNICATION OF INFORMATION IN JAPAN’S LOCAL GOVERNMENTS

Websites Operated by Local Governments

Japan’s local governments have each developed websites and operate them (hereafter, local government webs). The local government webs disseminate information about garbage disposal, Japanese-language lessons, and information about daily life and events.

Usually all the pages of the local government webs are created in the Japanese language. Only a few local governments have established web pages in English or Portuguese and added them to local government webs in the Japanese language. These special web pages have accurate expressions as they have been translated by translators (human) and have high reliability. However, the amount of information displayed on these special pages is much less than the amount of information on the entire local government web in the Japanese language.

Recently, some local governments have introduced MT and the initiative to display the Japanese-language local government web itself in multiple languages is starting. Although, MT

is not accurate enough, a lot of information gets automatically translated in one click. Majority of the local governments that have introduced it support not only English but about five languages. If MCRs are living in an unknown culture, communication of information about the local culture through MT should be very useful. Nevertheless, not all the web pages of the Japanese language local government webs are suitable for MT.

The following survey was conducted to shed light on such “case studies that are incompatible” with MT.

Survey

In this survey the following three points were confirmed based on the observation of local government webs.

- Status of provisions for multicultural co-existence in the cultural and comprehensive plans
- Status of provisions related to communication of information in multiple languages in the cultural and comprehensive plans
- Status of dissemination of ordinances in multiple languages

The target of the survey were cities and special wards among local governments where the composition ratio of MCRs was more than 4% taking as basis the “Basic Count of Population” in the population census conducted by the Ministry of Internal Affairs and Communications in 2010.

In the 2010 population census (Ministry of Internal Affairs and Communications, 2010), the municipality with the highest composition ratio of MCRs in the population was Kawakami Village at 15.7%. The next highest was Oizumi Town at 13.0%, followed by Nanmoku Village at 11.4%, Shinjuku Ward at 7.9%, and Minokamo City at 7.7%. Towns and villages are local governments but as the scale of the population and finance is small and the number of employees are also few, the administrative services are not so substantial.

Therefore, in this survey, towns and villages are excluded and cities and special wards are targeted for study.

This survey was conducted in May 2016.

Survey Results and Discussion

Table 2 shows local governments that fulfil the abovementioned requirements. There were 15 cities and special wards targeted for the survey. Among these, Shinjuku Ward in Tokyo had the highest number of MCRs at 7.9%.

Table 3 shows the presence of publishing of “cultural plans” focusing on culture in the survey targets. Six cities or 40% of them had cultural plans published.

Further, in Table 3 shows the status of provisions for multicultural and multilingual communication of information in the plans of the local governments.

In the survey, in case of local governments that have not published cultural plans or who have published cultural plans but do not have provisions, the highest level plans, that is, the comprehensive plans (also called basic plans) of local governments were confirmed.

As a result, there were four local governments who had made provisions regarding multicultural co-existence, and eight local governments who had provisions in the comprehensive plans. Therefore, a total of 12 local governments had made provisions in any one of the plans. This constituted about 80% of the 15 local governments.

On the other hand, three local governments had made provisions for multilingual communication of information and five had made provisions in the comprehensive plans. A total of eight local governments had made provisions in either one of the plans.

If these are reviewed, provisions for multicultural co-existence were incorporated about 50% in the comprehensive plans and about 60% in the cultural plans, and provisions for multilingual communication of information were incorporated about 33% in comprehensive plans and about 60%

Table 2. Cities and special wards with more than 4% in the population composition ratio of the foreigners

Rank	City/Special Ward(-ku)	Prefecture	Composition Ratio of Foreigners (%)	Nationality Except Japan (Total Number) (People)	Total Population (People)
1	Shinjyuku-ku	Tokyo	7.9	25, 742	326, 309
2	Minokamo City	Gifu	7.7	4, 189	54, 729
3	Minato-ku	Tokyo	6.3	12, 999	205, 131

in cultural plans. It was estimated that local governments that had developed and published cultural plans had a high awareness of culture compared to local governments that had not developed or published them.

Table 4 shows the status of multilingual communication of information on websites operated by local governments and the status of multilingual communication of information of ordinances. Almost all local governments were conducting multilingual communication. On the other hand,

there were no local governments found that were conducting multilingual communication of ordinances.

PROPOSALS

From this survey, in local governments with a high composition ratio of MCRs, even though there were local governments that stated the necessity of multicultural co-existence and multilingual

Table 4. Current status on multilingual Web and multilingual ordinances on the Web of 15 local governments shown in Table 2 (Unit: City/Special ward)

communication of information, there were no local governments that disseminated multilingual information about ordinances on the web.

For co-existence with MCRs, it is important to have a bi-directional compromise, that is, both an understanding of the culture of JRs and an understanding of the culture of the concerned region of MCRs. Ordinances are norms of daily life determined by the JRs and are simply the local culture. Measures that enable MCRs to understand local culture that is not easily visible in daily life such as ordinances are inadequate.

There are four points that can be considered factors for this situation.

- The style of the ordinances is strictly prescribed. As the ordinances are created using word processing documentation software such as Word, each local government uses a consistent style and the number of rows, characters, and indentation are implemented. When published on the web, these styles collapse.
- Ordinances prescribe rights and obligations and if accurate translation is not done, it can be misleading for the reader and there is a risk of hindering rights and obligations in some way.
- As for ordinances that are revised a number of times each year, translations by a translator (not machine) cannot be performed on time.

- As special applications are used for ordinances, it is possible to view not only the latest ordinance but also the history of past revisions. In ordinances with several revisions, this function of being able to quickly view the ordinance before the revision is very useful. In order to do machine translation without disturbing this function, for all ordinances, it is essential to recreate, in the web base, the current as well as the past ordinances prior to revision.

Hence, in this section we propose the following four points.

- Regardless of existing styles, it is important to disseminate ordinances focusing on content. So as not to interfere with the exercising of rights and obligations, it is more critical to make the content known than to adhere to the format.
- As machine translation is not suitable for ordinances, Japanese residents who are skilled in the specific language and MCRs can collaborate and come up with a proper human-powered translation. In this process, it is important to invite language experts such as translators and listen to their opinions as advisors.
- It is extremely difficult to conduct human-powered translation of all ordinances accurately and in a timely manner. Local gov-

ernments have established all ordinances systematically. In the system, basic ordinances are top priority and other ordinances are placed lower than other ordinances (Isozaki, 2012). Local governments should conduct multilingual information dissemination on a priority basis from basic ordinances that constitute the basis of the community. In recent years, 20% of local governments in Japan have prescribed the “fundamental ordinance on local autonomy” (Kurata, N, Kurata, Y, and Ohashi, 2016). These ordinances tend to be positioned at the highest level as the “constitution” of the concerned local government (Tsujiyama, 2002; Kisa, & Osaka, 2003). Therefore, it is expected that local governments that have prescribed the fundamental ordinance on local autonomy translate this ordinance on a top priority basis.

- It is mostly researchers, or government officials who create amendments for the ordinances that need the prior-to-revision version of the ordinance. It is fine to limit the display of revision history to the internal administration or to its use in the intranet. On the web, information dissemination for MCRs should be prioritized and only the latest ordinances that can be machine translated should be displayed in the web base. In order to exercise rights and obligations, there is no problem if latest ordinances are displayed as long as they are not litigation measures.

FUTURE RESEARCH DIRECTIONS

Among the abovementioned proposals, the process of creating translation in collaboration with MCRs can also be considered to contribute to the development of artificial intelligence.

In other words, if one considers the definition of artificial intelligence in detail, the following two perspectives exist. (Sugawara, 2007)

- Scientific viewpoint: Artificial intelligence aims to reveal the principles of intelligence and thought processes and explain them. Computer technologies are used as the means of manifestation of this theory. It is based on philosophical and psychological research methodology.
- Engineering viewpoint: Artificial intelligence refers to technologies that enable machines to operate things in ways similar to the use of intelligence by humans to operate things. For this, the human information processing functions are the model for computer-processable formats which are then put to use.

The process of translating in collaboration with MCRs, from the point of view of scientific definition, contributes to “revealing the process of understanding of an MCR who understand Japanese to a certain extent”. Also, the completed ordinances become an example and can be useful for example-based machine translation. If modeled, it can also be useful for statistical machine translation and can be considered as contributing to the engineering definition.

Further, as the native languages targeted in this survey are a few in number, the author would like to conduct further research in local governments with high composition ratio of MCRs.

CONCLUSION

Co-existence with MCRs is a challenge all over the world. In Japan where immigration policies have not progressed, multilingual communication of information is lacking. Specifically, since informa-

tion related to rights and obligations specified in ordinances differs depending on the local government, this information is not disseminated even though it is local culture that MCRs must know.

For the realization of a mature society that recognizes diversity, measures that facilitate the understanding of the local culture are first important. In order to protect the dignity of the MCR, it is essential to disseminate information to MCRs in an easy-to-understand language.

KEY TERMS AND DEFINITIONS

Artificial Intelligence: This refers to technologies in which intellectual activity such as understanding or reasoning of languages, and problem-solving skills conducted by humans are performed by computers instead. It is also called AI. Application fields that have incorporated artificial intelligence include expert systems that organize a particular area of human knowledge, store it as data, infer and judge using data, while understanding the meaning of inquiries. Further, artificial intelligence technologies are also utilized in pattern recognition that understands languages spoken by human beings and handwriting and in machine translation systems.

Fiscal Year: In Japan, the majority of companies, city halls, and schools operate according to the fiscal year. One fiscal year is from April to March next year.

Fundamental Ordinance on Local Autonomy:

The ordinances are regulations which each municipality enacts at its own discretion, the enactment of which is not obligated by the law of the national government. In the ordinances, the participation of citizens in community planning, along with provision of information relating to the community from the government to the citizens, are provided for, and provisions on administering the local area with citizens, local governments, area businesses, and organizations such as NPOs working together are spelled out. In many municipalities which have enacted them, the ordinances are positioned as supreme law which takes precedence over other regulations.

Local Government: This refers to municipalities and special wards established by the stipulations of the local government of a region. It refers to a local public organization whose boundary is of a smaller scale than that of a prefecture.

Machine Translation: This refers to the use of computers to translate into other languages. As translation of natural languages can contain several mistranslations due to omissions of words or mode of expression, it is used most often in the translation of technical documents such as manuals. Currently, it is sold as an application using the technologies of AI (artificial intelligence), and services are provided on the web pages.

Ordinance: Ordinances are government legislations applied in the prefecture or the local government, and are enacted within the range of the country's laws and regulations. A vote is required in the assembly of concerned local public organizations. In the prefecture or the local government, rules come under ordinances and guidelines come under rules. Among these, only ordinances require the decision of the council. As items related to the rights and obligations of the citizens are prescribed in ordinances, it is essential that they are enacted through a democratic process.

Population Census (National Population Census): This refers to the population survey conducted by the Statistics Bureau, Ministry of

Internal Affairs and Communications every five years on October 1 as of date. Questionnaires are mailed to each household and the members of the household answer providing the family composition. From 2015, it has become possible to provide answers via the internet as well. For

households that do not respond, survey officials appointed by the municipality personally visit the site and confirm the family composition among other things. According to the 2015 survey results, answers through the internet survey constituted 36.9% of the total number of households.

S

Vitalizing Ancient Cultures Mythological Storytelling in Metal Music

Uğur Kiliç

Ondokuz Mayıs University, Turkey

INTRODUCTION

The myth, which has been emerged at first because of the need of the humans “to understand”, then “to let the others to understand” by narrating, has a language structure full of symbols. This narrative characteristic of the myths leads this narrative genre to have a dynamic structure impeding it to be stuck in a certain period of time. Thereby, the myths have gotten a foothold existing in different narrative genres, and have even become a culture all by itself.

For instance, as the most known example, Classical-era Greek Mythology has been a part of the Western culture for centuries. It is known that Greek mythology has reached to this day nourishing various narrative genres. Aforementioned mythology is still in action in those genres thanks to its symbolic structure. Mythology enriches its own universe by interacting with different narrative genres. In fact, writers, artists and intellectuals have enhanced this enrichment including mythology in other fields such as literature, painting, sculpture, philosophy, theatre and music for centuries. The use of mythological motif in a work of art not only fosters the culture that it has emerged into, but also leads to a positive result for the recurrent mythology.

Today, the myths are used being included in different narrative genres. Thus, myths still continue to be active in cultural production. For instance, one can find traces of mythology in academic studies, literature, fine arts, theatre, computer games, TV series, movies and music. As it is seen, myths are positioned as a discipline

that protects its dynamics in expressional fields, e.g., literary, visual and audio.

Today, the other factor that ensures that myths being active in the cultural field is the myths of different geographies can be included in the production field thanks to the increasing number of various narrative mediums in modern day. While in the past the motifs of the dominant narratives, e.g., Greek and Roman Mythology, were mainly used in the works that were created, in today’s world almost every mythology that has been found and put together by studies may find itself a place in the cultural production. The narratives ranked among mythologies like Egyptian, Celtic, Norse and Hindu Mythology, used in fields like literature, films, painting and music is presented as an example for this statement.

The relation between music and mythology gets ahead of aforesaid narrative genres. The most important reason of this pioneering position of music is that music, just like mythology, is one of the ancient forms of narration. Music, whose origins go back to the sounds of nature, has a history of thousand of years. Cavidan Selanik (2010) defines music as “...with the aim of thinking with sounds, feeling and enhancing life through sounds, the art of researching and narrating the reality of man in all of its contexts”. The desire of man to narrate the facts and the events around him with the aim of feeling and enhancing life is similar to the starting point of mythology, inasmuch as myths also emerged thanks to the effort of man to interpret and narrate ‘the things’ happening around him.

Among the music genres of this day, number one genre that includes mythology and the myths in its area of usage is metal music which has begun to evolve around the UK and the USA in the late '60s and in the early '70s. Many bands in the history of metal music have used mythology in their lyrics, the video images, on the album covers, for their costumes and stage shows. Hence, mythology is renewed and enriched also in today's cultural production process. The relation between two of the most ancient narrative genres, mythology and music, which maintains on a contemporary level, is a subject that has been manifested to be studied about.

Based on the manifested research subject, it is intended that the subjects of metal music and mythology are of the top priority to be analyzed. In the chapter of praxis, in the aim of showing the connections of mythology, the lyrics, album covers, videos and concert performances of contemporary metal bands such as Amon Amarth, Eluveitie, Týr, Therion will be analyzed briefly. In addition to the praxis, Swedish metal band Amon Amarth's album "Twilight of the Thunder God" (2008) will be studied using semiotic method of analysis.

BACKGROUND

In this study, principally the conceptual framework will be specified by surveying literature reviews on 'metal music' and 'mythology'. In the praxis, semiotic analysis will be practiced upon. The reason of utilizing this method is that the band Amon Amarth enables us to read and study the mythological images on their album cover under the light of semiotic analysis, inasmuch as the reading method which semiotic analysis offers, assists us to reveal the mythological meanings in the visual product that the band released.

As it is known, the fundamental principles of semiotics depend on the studies of Swiss linguist Ferdinand de Saussure and American philosopher Charles Saunders Peirce. Saussure approached se-

miotics within the limits of linguistics. According to Saussure, a sign is composed of the signifier and the signified. The signifier is the image of sound that the message is ensured to be heard by the receptor. The signified is the meaning that occurred in the receptor's mind (Atabek & Atabek, 2007). The connection between the signifier and the signified is created by the rules and the codes that the society has determined. Dyer (2010) explains the arbitrariness between the signifier and the signified as: "The signifier isn't similar to the signified or the signifier doesn't cause the signified, but they are related by convention or 'contract' ".

On the other hand, Peirce made a connection between semiotics and logic, and saw every subject he had researched as a phenomenon of semiotics, and established the theory of signs in this context (Atabek ve Atabek, 2007). Peirce divided semiotic, which he argued that logic is formal semiotic, into speculative grammar, logic proper and rhetoric. In addition to that, Peirce divides the 'sign' itself into three. These are icon, index and symbol (Rifat, 2009). Icon is the sign that appears to have a similarity to the object (e. g., picture or photograph); index is the sign that is directly related to the signified (e. g., smoke, footprint); symbol is the sign that has a relation of arbitrariness with the object (e. g., flag, traffic lights)" (Atabek & Atabek, 2007). The arguments of Saussure and Peirce pioneered the development of semiotics. Thus, many semiotical applications that improved the conceptions of Saussure and Peirce have come to light since '20s. For instance, the semioticians in Europe have tried to contribute to semiotics based on the ideas of Saussure.

One of these semioticians, L. Hjelmslev, re-considered the bilateral of 'signifier/signified' and 'form/substance'. In this context, Hjelmslev named them as the expression plane, which includes the substance of sound, and content plane, which is the conceptual manifestation of the sign, and he also distinguished between form and substance. According to Mehmet Rifat (2009) in terms of the semiotic studies, one of the crucial conceptual

dualities of Hjelmslev is ‘denotation and connotation’. “Simply it means that any linguistic unit contains other and novel meanings (i. e., connotation) beyond its literal meaning (i.e., denotation).” Another semiotician who argued about the content plane is Roland Barthes (Fiske, 2003). “According to Barthes, who reorganized the distinction of Hjelmslev’s denotative semiotic, connotative semiotic and metalinguistic semiotic with a few small alterations, signs may refer to connotations that have other meanings apart from their denotations” (Atabek & Atabek, 2007).

To sum up, semiotics can be defined as ‘the key to any type of semantic coding system that allows communication to occur’. “Code is the semantic system that a culture or subculture members share” (Fiske, 2003). Thereby, semiotics sets a semantic structure manifesting the sign, the signifier and the signified in decoding.

Based on this possibility that semiotic studies allow, the praxis chapter of this study begins with the iconic explanation of the album cover. Iconic explanation is the part in which the images on the album cover are described and the locations of the images are pointed out. After the iconic explanation, signs are analyzed as signs at primary level, signs at secondary level and color code. In research of ‘signs at a primary level category’ the images on the album cover that draw the attention at first sight are determined. It is important to determine these images in terms of the explanation of the composition that has been put together on the album cover. In the category of signs at a secondary level, the rest of the images that is within the frame are explained. In the category of color code, the dominating color scale is analyzed and the meaning that is represented by this color is interpreted. Following this analysis, the visuals of the album are viewed in the terms of Denotation and Connotation, and they are analyzed in the context of ‘signifier of the denotation-signified of the denotation’ and ‘signifier of the connotation-signified of the connotation’.

On the other hand, in the praxis chapter it is aimed to support the analyzation with the ex-

amples of the album titles, the lyrics and stage performances of Amon Amarth because there are references to mythology in the song titles and lyrics stated in the albums of Amon Amarth. Furthermore, the band designs their stages in parallel to mythological narratives to support and recreate the content of their songs. Therefore, the analysis of these aforementioned elements is important in terms of revealing the connection between the band and mythology.

METAL MUSIC AND MYTHOLOGY: ROOTS AND CULTURAL CONNECTION

Since music is a cultural and artistic production, and it cannot be considered outside of the actions of the society that it has been emerged into, it is a product of thousands of years old adventure. Music has started to be formed by man having the sound in a thinking process and dominating it and has had various functions depending upon the societies’ transformations through historical process. Music, which is a product of thought, is related to the society and geography the person who engages with, and the mentality of the era it is produced in (Selanik, 2010).

By the 20th century, it has become harder to identify the characteristics of the history of music compared to previous periods. The main reason is that the developments in technology has enhanced various music genres in the same period of time. By the modern era, in consideration of technological resources with all the background it accumulated since the primitive age, music has continued to evolve zestfully, vigorously, and normatively at times. “Briefly, 20th century has opened up horizons for musical narratives, provided new instruments and in this context our era is the richest one in history of music” (Mimaroglu, 1999). Metal music, which this study has been bounded by, is a genre emerged under the light of these technological and socio-cultural changes, and in the pursuit of renewal.

Heavy metal or more widely known as metal music is a music genre which evolved in the late '60s and early '70s in the UK and the USA. In fact, the two mainstream genres are known as "New Wave of British Heavy Metal" and "New Wave of American Heavy Metal" surpassing all the subgenres. In this context, the majority of the bands that formed a basis for metal music and led the way in its early period is British and American (e. g., Black Sabbath, Led Zeppelin, Judas Priest, Iron Maiden, Alice Cooper). Aforementioned bands established the characteristics of metal music.

In technical terms, in the early years metal bands included a lead vocal, guitarist, bassist and drummer, later they have included another guitarist that played in sync with the ongoing guitarist creating a stronger and richer sound. In regard to the content, it is seen that various themes and subjects are used in metal music. For instance, in trash metal along with feelings like love, hate, fear and aggression, the variety can be seen in themes like fear of death, destruction, evil, mythological stories, creatures and themes belonging to horror stories (Charlton, 1990).

The technological means that constitutes the reason for the variety of musical movements in 20th century has had its share in also metal music, and these innovations that have been gone through since '70s has led the division of many subgenres, differentiation and disintegration in musical forms. The most well-known subgenres of metal are glam metal, thrash metal, death metal, black metal, folk metal and viking metal. Common trait of these subgenres is that they have created a universe and culture for metal music with the output they have generated. Any of this subgenre has benefited from the culture of the society it has emerged into, directly or indirectly. Folk metal and viking metal, which fulfill the aims of this study, are the proper examples on this topic.

Folk metal, emerged in Europe in '90s, is a genre of metal. Folk metal combines both traditional folk music and heavy metal and it includes

folk instruments in addition to heavy metal instruments. Themes of folk metal are generally nature, history, paganism, fantasy and mythology. In today's world, folk metal is popular especially in Europe. Finntroll, Ensiferum, Korpiklaani and Turisas can be seen as the prominent bands of folk metal. On the other hand, Swedish band Bathory that was formed in 1983 is the pioneer of viking metal. It can be said that viking metal utilized the elements of black metal and folk metal. This music genre adopted the pagan belief of Scandinavia, Norse mythology, the narratives of Viking Age, wars, epic tales and legends. Some of the viking metal bands, like typical folk metal bands, has been using Norse instruments (e.g., kantele) in addition to traditional metal music instruments. Although the lead vocal can be subject to change, brutal vocal is mainly used. Bands such as Wolfchant, Hel, Månegarm ve Týr are shown as the examples of today's viking metal. Considering the lyrics, album visuals, videos and stage performances of these two subgenres of metal music, mythological orientation cannot be overlooked. In order to reveal mythological traces of aforementioned genres, it is necessary to analyze mythology and its structure.

In history, human who is conscious and the most active being towards outside world has been trying to understand "the things" and find correlations between infinite number of phenomena. Knowledge that has been accumulated through this endless continuum, is a natural result of this mental and dynamic process that has been tried by the societies. It is possible to see this vast knowledge manifested in many fields as a production that meets the need of understanding, narrating and sharing of the humankind. Storytelling whose origins goes back to ancient times is the most efficient product of this need of narrating. According to Dell (2012), point of origin of mythology is based on the tendency of aforementioned "understanding and narrating of the origins of 'things'". The values of the societies, their views on concepts and phenomena they contemplated about were effective on the occurrence of the myths

of the societies. Yet, myths aren't just viewed as a part of storytelling. Instead, they are redefined from different perspectives.

It is likely to consider myths as “bo tree” that gathers their sacred values alongside with the lifestyle and wisdom of primeval communities, shaped by symbolic narratives. The myths that were shaped by the belief, lifestyle and wisdom that they were born in, although they seem like a narration medium that serves for the mental production of the individual, become important with the contributions to the culture thanks to the various elements they've been formed of. In other words, although the myths are man-made, they have the essence that characterise and guide the society in lots of ways because the myths are viewed as sacred, unlike the other narrative genres (e.g., tales, epic stories), by the society and therefore they become more efficient in people's lives.

Refusing the effects of the myths on the cultural production means refusing the society itself because when considering both modern and the archaic societies, one can find the traces of mythology in their language, daily lives, literature, art, sculpture and music. When discussing the connection of mythology with music, the first prominent study field is Greek mythology because of the etymology of “music”. Indeed, the origin of the word “music” goes back to nine goddesses known as the Muses or the Mousai in Greek mythology. On the other hand, not as many as in Greek mythology, but it is possible to track the traces of music in other mythologies. Eventually, there is a god or goddess that is related to music in all mythologies.

In today's world, the most obvious genre mythology is represented in music is metal music. Amon Amarth, Ensiferum, Turisas, Blind Guardian, Manowar, Hel, Heidevolk, Týr, Therion are some of the bands that use mythology in their music and distinguish themselves with this characteristic of them. Amon Amarth, who is analyzed in the praxis chapter, includes Norse mythology in every field of their music (e.g., lyrics, album images, stage shows and set). With this aspect of theirs,

the band has become important in cultural terms for producing music in aforementioned tendencies.

MYTHOLOGICAL STORYTELLING IN METAL MUSIC

As it was mentioned in the previous chapter, there is orientation toward mythology in certain subgenres of metal music. This orientation can be observed in lyrics, album titles and visuals, videos and stage shows. Amon Amarth, that is included in the praxis of this study, is a Swedish metal band from Tumba, Stockholm, founded in 1992. They released nine studio albums which are: *Once Sent From The Golden Hall* (1998), *The Avenger* (1999), *The Crusher* (2001), *Versus The World* (2002), *Fate Of Norns* (2004), *With Oden On Our Side* (2006), *Twilight Of The Thunder God* (2008), *Surtur Rising* (2012), *Deceiver Of The Gods* (2013). As it is clear in the album titles, the focus point of the band is Norse mythology. In fact, the title “Fate of Norns” represents The Norns in mythology which are female beings who rule the destiny of gods and men. The title “With Oden On Our Side” has a reference to god Odin. The title “Twilight of the Thunder God” connotes god Thor with the use of ‘thunder god’. The title “Surtur Rising” represents the the giant of fire, Surtr, in mythology. The title “Deceiver of Gods” connotes Loki who is characterised as a trickster god in mythology. As Imke Von Helden (2010) stated “Considering the content of lyrics, references to Norse mythology are seen to have given by viking metal bands.” The songs in Amon Amarth's albums are strong proof of this inference. Furthermore, when the band's albums are studied, it is seen that in all of their nine albums there are songs that include the motifs of Norse mythology. The references involve gods like Odin, Thor, Loki, Balder, Frej, Mimir, Hel, the creatures from different races like Surtr, Jörmungandr (*Midgard Serpent*), Fenrir, as well as toponyms like Yggdrasil, Midgard, Nifelheim, Muspelheim, Hel and narratives in mythology.

The symbols used in these narratives can be a transformed version of the mythological narrative or the exact version of certain parts of those narratives. As it is seen, the album titles have direct and clear references to Norse mythology. For instance, in the song “Twilight of Thunder God” Thor’s battle against the monstrous serpent Jörmungandr in Ragnarök has been depicted.

*Thor, Odin’s son, protector of mankind,
Ride to meet your fate, your destiny awaits.
Thor, Hlôdyn’s son, protector of mankind,
Ride to meet your fate, Ragnarök awaits!*

In the song “War of Gods”, as it is understood from its title, the war of gods in the Norse pantheon is described. This narrative, as it is studied in mythology before, is about Æsir-Vanir war, which are two groups of deities. In the lyrics below, it’s been told that after the Æsir-Vanir war, Mimir who has been sent to Vanir as a captive and his head cut off and sent to Odin.

*The Vanir failed to see Hænir was a fool
Without Mimir at his side Hænir could not rule
In a field of violent rage Mimir’s blood was shed
And to Odin’s court they sent Mimir’s severed head*

As it is seen, content of the lyrics of Amon Amarth as well as their song titles has references to various narratives and gods in Norse mythology. When one reads Norse mythology in depth, these references are identified one by one and one can see the correlations between the song and the mythology clearly. The other way Amon Amarth uses the visuals is stage designs. The band uses the decor and settings that are associated with mythical narratives in their concerts. The motifs associated with Norse mythology, the runes on columns in Old Norse language, the flags, and the hammer of Thor, Mjölnir are some of these decors. It is possible to watch the band’s decor use in 2013 in Summer Breeze Open Air heavy metal festival that takes place annually in Germany (<https://www.youtube.com/watch?v=IGeoJLIuow>). The band

used the decor of Jörmungandr in their stage show, in Wacken Open Air festival in 2014, which is an important festival for the metal music community that takes place annually again in Germany (<https://www.youtube.com/watch?v=mHCNfGQZpG8>).

The most apparent traces related to mythology in metal music are to be found in the album visuals of the band. Hence, one can see an example of this in the album visuals of “Twilight of the Thunder God (2008)” (<http://amonamarth.com/deceiver-of-the-gods/>) Considering the content of the album, the songs and the mythological references in those songs are: Twilight Of The Thunder God (*Jörmungandr, Thor, Odin, Hlôdyn, Ragnarök, Mjölnir*), Free Will Sacrifice, Guardians Of Asgard (*Asgard*), Where Is Your God?, Varyags Of Miklagard (*Norns*), Tattered Banners And Bloody Flags (*Loki, Æsir, Yggdrasil, Muspel, Midgard, Nifelheim, Fenris – Fenrir, Heimdall, Odin, The Norns, Valkyrie*), No Fear For The Setting Sun, The Hero, Live For The Kill, Embrace Of The Endless Ocean.

The album cover of Amon Amarth’s “Twilight of the Thunder God (2008)” contains a digital image. A dragon-like serpent is seen on the right side and the subsection of the frame. The mouth of the serpent is open threateningly and is faced to the man that holds its tongue. The man is standing on the curves of the serpent in the middle of the frame. The man has long and blonde hair and beard. The man has warrior clothing and the belt that hold it together on him. The man holds a short and shiny hammer, which has runes-like engravings on, in his right hand. He is holding the serpent’s tongue with his left hand. His posture gives the impression that he’s about to hit the serpent with the hammer in his hand. The ocean-like imagery takes place up to the middle of the frame and around the serpent and the man. The flames and thunders on the rough water can be seen. An effect like rain and thunder draws attention and stormy sky colors are dominant all across the frame. On upper left side of the frame, the name of the band (AMON AMARTH) is written with the color of flame and rune-like fonts. Under the

name of the band, the album title with smaller fonts (TWILIGHT OF THE THUNDER GOD) is seen.

- **Signs at Primary Level:** The serpent and the man with the hammer holding its tongue. The size of the serpent and the dragon-like appearance are the signs of a mythological creature. The man represents a warrior with his clothing and the hammer. In addition to that, the imagery of the man's battle against a mythological character and his engraved hammer in his hand gives the impression that he's a mythological sign/character as well.
- **Signs at Secondary Level:** The ocean, the flames and the thunder. The rough and stormy ocean is the sign of danger. The flames beyond the ocean are the images that support the notion of danger and threat. The lightnings are the signs of storm, thereby they altogether support the chaotic atmosphere created by the flames and the stormy weather.
- **Color Code:** The dominant colors in the image are the mixture of black and grey, tones of twilight and red. The colors that constitute twilight represent pessimism and death. The redness of the flames is the sign of terror and danger.

The dragon-like serpent and the man with a hammer holding the serpent's tongue appear in terms of denotation on the album cover of *Twilight Of The Thunder God* (2008). The man represents Thor in the Norse mythology and the serpent he attacks represents Midgard Serpent (*Jörmungandr*) existing in the same myth. The hammer in his hand and the belt indicate that he is Thor because the belt stands for Thor's power-belt and the hammer stands for his sacred weapon, Mjölnir. The dragon-like serpent that we see in various parts of the frame stands for Midgard Serpent that will make the world end, alias *Jörmungandr*, in Norse mythology. Thor and the flames, storm and the lightnings behind Midgard

Serpent give the impression of chaos. According to Norse mythology, Thor and Midgard Serpent battle against each other on judgement day, i.e., Ragnarök. Therefore, the images of the lightning, the flames and the storm in the frame represent the judgement day, i.e., Ragnarök. The lightnings are the signs of god of lightning, Thor, as well.

Looking at the image, tones of black and grey are dominant in general. This toning on the twilight is another supporting sign of Ragnarök in the frame. The writings on the upper left side are the information about the band's name and album title.

As it is seen, *Twilight of the Thunder God* (2008) is abundant in mythical symbols. It must be known that analyzing just one album cannot let us generalize the mythological effect on metal music. However, analyzing the other eight albums of this band, one cannot avoid discovering mythical symbols. Furthermore, Amon Amarth is not the only band that includes mythology in its music production. For instance, Týr, the metal band from Faroe Islands, is another band that produces music using mythology. One can see clearly the first step of using mythology is the band's name which is a god in Norse mythology. In fact, the albums of the band such as *How Far To Asgaard* (2002), *Ragnarok* (2006), *The Lay of Thrym* (2011) and *Valkyrja* (2013) incorporate mythical symbols directly in terms of both the names of the albums and the lyrics (<http://www.tyr.fo/discography>). And also, Swedish symphonic metal band Therion's album *Secret of the Runes* (2001) is directly related to Norse mythology in terms of album cover, the names of the songs and the lyrics (<http://therion.se/discography/secret-of-the-runes-2001/>). And another contemporary example of the use of mythology in metal music is Swedish folk metal band Eluveitie (<http://eluveitie.ch/discography/>). Eluveitie includes symbols of Celtic mythology in their albums they have released until today.

Consequently, analyzing the album names, the lyrics, album images and stage performances of the bands that have been included in the praxis of

this study, mythical symbols are included in music production by those bands. Indeed, the elaborate analysis of the band Amon Amarth supports this argument.

FUTURE RESEARCH DIRECTIONS

Technological developments in music increase the control on “sound”. Thus, metal music bands strengthen mythological stories in both lyrical and sound dimension. In today’s world metal music can be considered as an uncharted territory for communication, semiological, mythological and sociological studies. Many metal music bands produce their music adopting various symbols, languages and philosophical approaches. On that sense, every subgenre of metal music, in fact every metal music band, represents a whole universe of subculture. Semiological analysis in this study shows that mythological images can be examined in many form in metal music bands. Every interdisciplinary study in the academic field will act as a key for the secret door of metal music that has been waiting to be opened. In recent years the fact that mythology has been used mostly in metal music is another subject that must be studied in depth. Inasmuch as these tendencies of music bands, the attitudes of the audiences towards those tendencies and the desires of them must be analyzed. The academic studies in mythology and music will be useful for explaining today’s cultural changes.

CONCLUSION

Every society has its own myths and every myth has its own messages in its limited capacity. Those myths that narrate nature, creation, death, belief, war, chivalry, morals; to be brief, life, includes various experiences and wisdom that existed all around the world. For instance, Greek, Celtic, Turkic, Egyptian, Norse and lots of other mythologies have different classifications, functions and

also symbolic narratives. The myths, with their rich contents, have been a source of inspiration full of mental and spiritual elements for languages of today’s and the past societies, daily life, literature, art, sculpture and music. It is possible to observe the reflections of mythology in every field of literature, cinema, television and music. Music is another cultural production for mental and spiritual satisfaction. Thus it’s recognized as a very crucial point in this study.

This study has been limited to metal music which is a music genre that emerged in the late ‘60s and early ‘70s led by the United States and the United Kingdom with the technological, socio-cultural changes and innovative researches. As in lots of music genres, in time various subgenres began to appear in metal music in terms of content and technique. It is possible to say that certain subcultures have come forward as a result of adopting the subgenres of metal music in society. Because of their differences of content, style and technique, the subgenres of metal music such as glam metal, death metal, black metal, folk metal and viking metal are accepted as the subgenres that shape their own culture of music and listeners. Metal music which has been diversified with different equipments in terms of content and technique, has become important for this study owing to the inclusion of mythology.

As it’s been regarded in the praxis study, the birth of music and mythology go back to ancient times, and today they are two narrative systems that keep on building up, renewing and reviving. Myths are the first examples of storytelling and music, which continues to help its survival in its own possibilities, and they still share the same platform in the productions of metal music bands. Metal music bands play the part of today’s ‘mythological storytellers’ using mythology. Thus, mythology and music carry on playing an active role in cultural production. This deduction approaches mythology to metal music more and manifests the need for further study to determine the reflections of mythology on various subgenres of metal music.

KEY TERMS AND DEFINITIONS

Connotation: It represents the secondary, suppressive meaning of a sign, that is related to the personal knowledge of the one interprets the sign with.

Denotation: The first and direct meaning of a sign.

Jörmungandr: In Norse mythology, the serpent that lives in Midgard, the world inhabited by humans, and that Thor will battle against on judgement day.

Loki: The god that represents evil in Norse mythology.

Mjölknir: The magical hammer that belongs to god Thor in Norse mythology.

Myth: A narrative genre that explains the values of a society (its belief, philosophy, lifestyle, guidance, art etc.) it emerges into through supernatural events and people.

Norns, The: The female beings who rule the destiny are named Urd, Verdandi and Skuld in Norse mythology.

Odin: The main god that is “the father of all things” in Norse mythology.

Ragnarök: Judgement day in Norse mythology.

Thor: The most powerful god in Norse mythology.

Mining Sport Activities

Iztok Fister Jr.

University of Maribor, Slovenia

Iztok Fister

University of Maribor, Slovenia

INTRODUCTION

For many people today, sport is one of the stress relieving activities. People usually get involved in sport to achieve attractive shape, healthy lifestyle and better feeling. However, some people get involved in sport to compete professionally. Competitions were recently reserved for the professionals only. Few years ago, the professional community became more open to amateur athletes whose main objective is not competing. Nowadays, these can join to professional sports communities (Rauter, & Doupona Topič, 2011). Especially in massive sports events (running marathons, triathlons, cycling competitions), organizers give the opportunity to amateurs for competing with professionals in the same competition.

Amateurs need to train properly in order to fulfill their competition goals. Performing hard training is difficult not only for amateurs, but even for professionals. Athletes usually train at different stages and places to improve the effectiveness of training – gym, fitness, swimming pool, road, macadam, etc. Another obstacle that usually makes planning sports training sessions difficult for amateurs are properly balancing the two typical training phases, i.e., resting and eating that accompany each end of the training session. Consequently, athletes need to hire personal sports trainers in order to continuously improve their performance. Unfortunately, this hiring becomes very expensive after some time for amateur athletes.

Recent expansion of smart sports watches and smart phones allow athletes to carry out the sports training sessions smarter. Usage of mobile devices

(Baca, Dabnichki, Heller, & Kornfeind, 2009, Baca, Kornfeind, Preuschl, Bichler, Tampier, & Novatchkov, 2010) typically causes production of the dozens of activity datasets containing data about athlete's position, speed, heart rate and power rating over the sports training sessions. Analyzing these activity datasets enable an athlete to gain the deeper insight into every training session. Furthermore, a computer program using the latest data mining methods is even able to extract athlete's habits during sports training. Moreover, it may notify the athlete for possible over-training syndrome to prevent injury, advice nutrition using prediction and in the end, generate various sports training plans by clustering similar activities together.

Consequently, there is a lot of possibilities how to use these data for a further analysis and apply them for improving the athlete's performances. In a nutshell, these activity datasets offer an infrastructure for developing the artificial sports trainer (AST) as proposed by (Fister, Ljubič, Suganthan, Perc, & Fister 2015) that will be capable to help athletes during all sports training phases. Unfortunately, the most of athletes (especially amateurs) are not familiar with sports training theory and thus every assistance in any phase of sports training is welcome. As a matter of fact, the proposed AST computer framework based on Computational Intelligence (CI) algorithms that is open and therefore suitable for incorporating the new features easily.

The primary objective of the AST is to generate the sports training sessions of similar quality as a real trainer. At the moment, the AST serves as a

Figure 1. Illustration of training plan generation in the past and future

framework in which a various features covering different phases of sports training are incorporated especially in individual sports disciplines, where a lot of sports activities have been tracked using the wearable mobile devices. It definitely will present a bright star in planning, performing, controlling and evaluating phases of the sports training also in team sports disciplines in the future.

In this chapter, we focus on opportunities of data mining in sports. In line with this, the association rule mining method is proposed that was applied up to the present for solving two problems, i.e., discovering hidden habits of athletes in sports training and detecting the over-training syndrome. The results of both applications showed a true potential of these methods for data mining the sports activities. However, both applications can be incorporated in the AST framework as the features in the future.

Organization of this chapter is as follows. The next section is devoted to highlight background and fundamental information. In line with this, sports trackers and data mining paradigm are discussed. Then, the principles of data mining the sports activities are clarified. After that, the current applications in mining the sports activities are discussed shortly. The article concludes with a discussion and future research directions.

BACKGROUND

Sports Trackers

In order to track athlete's sports activities in the past, running athletes had worn very simple

watches (later renamed to simple sports watches). These watches allowed to monitor only time and were therefore used for analyzing the duration of workouts and interval trainings. One of the pioneers of sports watches, the finish manufacturer Polar, released first sports watch enabled measuring and monitoring the heart rate in 80's. Heart rate monitors allowed heart rate measurements in a real-time, thus allowing athletes to adjust performance in training/race. Heart rate was also stored into sports watch's memory suitable for the later analysis. Consequently, all measured data helped athletes to perform better training and competition by achieving much better results. At the beginning of the last century, the huge expansion of cycling sensors for measuring a speed and cadence in real-time emerged. The manifestation of those sensors improved also cyclist's performance. Today, modern sports bike is equipped with so called power meter. Power meter offers real-time power monitoring, and nowadays presents the state-of-the-art technology in cycling.

Another revolution was born with an emergence of mobile and pervasive computing. The mobile devices have been renamed to sports trackers when a massive production of smart phones and appropriate software applications has started. Sports tracker is basically an application running on the smart phone in order to track a sports training session (Fister, Fister, Fister, & Fong, 2013). These mobile devices obtain information from a global positioning system (GPS). There is a lot of sports watches on the market equipped with GPS that behave almost the same as the sports trackers (e.g. Garmin Forerunner, etc.). Consequently,

today's almost every type of sports training sessions can be monitored using the sports trackers (even swimming). Data about sports activities can be uploaded to the internet after finishing the training sessions. Powerful software applications allow the online analysis of these training data, sharing sports activities with friends in a "social network" and rearranging virtual competitions between these. Much more functions are accessible to users, e.g. weight monitoring, commenting on social networks, pace prediction and personal records storing. Data tracked during the workout is actually written into the XML datasets. There are two special formats of sports training datasets:

- GPX (GPS Exchange Format) (Code snippet 1),
- TCX (Training Center XML) (Code snippet 2).

The first code snippet presents an example of the GPX dataset, while the second an example of the TCX dataset. Both formats are easily for parsing, i.e., extraction of parameters. In fact, there are many tools which allow researchers to extract features from datasets. How to deal with these data is outlined in the paper (Rauter, Fister, & Fister, 2015).

Data Mining

Data mining (Han, Kamber, & Pei, 2011) is a popular discipline of computer science dealing with information extracted from large databases. This means, data mining methods help us to discover knowledge hidden in data. These methods have become more popular in the current era of big data. In line with this, various data mining applications were developed for application in

business, finance, medicine, engineering and even sport domain. At the moment, the most frequently used methods in data mining encompasses:

- Classification,
- Clustering,
- Association rule mining and
- Regression.

Classification is a process of searching a model for describing data classes or concepts. The model is built using an analysis of learning dataset, where the results of classification are known. This learned model can be used for prediction of test dataset, where the classification results are unknown. Clustering enables an integration of similar data into the so called clusters

Figure 2. Mining sports activities

and does not use any output variables (Jain & Dubes, 1988). Association rule mining searches for relations between attributes that stay normally hidden in databases. Regression differs from the classification in the number of output variables, because there is only one output variable. The most popular classification methods are: support vector machines (SVM) (Vapnik, 1998), decision trees (DT) (Quinlan, 1986) and artificial neural networks (ANN) (Gershenson, 2013). Interestingly, a high impact of nature-inspired algorithms tailored for data mining tasks (Fong, 2013; Fister, 2015) is increased.

MINING THE SPORTS ACTIVITIES

Mining the sports activities (Figure 2) offers athletes to get a deeper insight into their own characteristics, like a body capacity, physical conditions, mental abilities, etc. Usually, casual sports trainers measure a training load of an athlete indirectly by using some indicators of sports training intensity, like heart rate, lactate, VO2 max etc. An estimation of the athlete's progress and increasing the performance over the years bases directly on tracking this information.

Typically, athletes do not realize any insight in relations between indicators of sports training intensity that are saved into dataset as attributes.

Knowing these relations (also associations) could have a great impact on an improvement of the athlete's performance. For example, the athlete performing the sports training session of medium duration, but high intensity will normally sleep badly that day. He will probably not regenerate till the next day. On the other hand, the same athlete will feel motivated and will have good eating habits after performing the long training session of low intensity.

Shall we find any special relations between attributes in large databases, and thus the athlete is guided to be motivated for sports training and consequently influences on his/her faster recovering? Of course. Using one of the data mining methods, named association rule mining, these hidden relations can be discovered. However, some of the association rules presents the positive relations that need to be promoted by the trainer, while another determining the negative relations should be prevented by trainer. For example, if an athlete has problems with eating and sleeping (consequently bad recovering) after the interval training session, he/she can still decrease the load or shorten the duration of the training session.

Mathematically, the association rules are expressed as an implication $X \rightarrow Y$, where X and Y are two subsets of items $I = \{i_1, \dots, i_n\}$, and $X \cap Y = \emptyset$. In addition, a set of transaction

named dataset $D = \{t_1, \dots, t_m\}$ is defined, where each transaction has unique identification and contains a subset of items. Typically, each mined rule is estimated according to the set of transactions by two measures, as follows:

- Support, which is defined as proportion of transactions containing X and Y , and the total number of transactions in database, i.e.:

$$\text{supp}(X \Rightarrow Y) = \frac{n(X \cup Y)}{N}$$

- Confidence, which is defined as proportion of transaction that contains X also contains Y , i.e.:

$$\text{conf}(X \Rightarrow Y) = \frac{n(X \cup Y)}{n(X)}.$$

Thus, the support must be higher than the prescribed minimum support $S_{\min}$ and the confidence higher than the prescribed minimum confidence $C_{\min}$.

Let us notice that there is a lot of association rule mining methods. Anyway, the procedure of the proposed mining sports activities consists of the following four steps:

- Data collection, preparation and preprocessing,
- Selecting the proper association rule mining method,
- Applying the selected data mining method to extracted data and
- Presenting the results to athletes or trainers using visualization.

In the first step, data needs to be prepared. Obviously, sports training datasets are collected by athletes over many years. All these tracked data

about past sports activities should be imported into databases. It is a good practice by athletes to add some additional information about present training session in a form of short questionnaire. Questionnaire describes some characteristics about athlete's feeling (e.g., eating and sleeping after training).

After the importing data about past training session, the proposed method for mining the sports activities is ready for preprocessing. The aim of the preprocessing is to extract attributes from data. These attributes are values extracted from the corresponding activity datasets (Rauter, Fister, & Fister, 2015) and questionnaires, as for example: total duration time, total distance, average speed, average and maximum heart rate and others. The structure of preprocessed features depends on the selected data mining method later. Extraction of these features are presented by various parsers that are described in paper (Rauter, Fister, & Fister, 2015).

In the second step, a decision needs to be received, where the expected results of the data mining should be determined. Consequently, a proper association rule mining method must be selected in the step. For example, if the athlete's behavior during or after training session is necessary, then the methods, like Apriori (Agrawal, & Srikant, 1994) or BatMiner (Fister, 2015), should be used. While the former is the traditional method, the later bases on the known swarm intelligence algorithm. According to the selected data mining method, the preprocessed data should be prepared.

The purpose of third step is to apply the selected data mining method to dataset, in other words, the selected data mining algorithm is being to run.

The final step is devoted to visualization of results to athletes or sports trainers. This step is very important due to successfully presentation of results obtained by the data mining method. Human are visual beings to whom the visual information say more than equivalent alphanumerical information. Therefore, the visualized, graphical information are more suitable for presentation of

Figure 3. An example of association rule

the results. One of the more popular possibility for graphical presentation are glyph-based diagrams (Ward, M. O. 2002).

CURRENT APPLICATIONS

Recent efforts in mining sports activities domain revealed two interesting applications for mining the sports activities:

- Finding hidden habits of athletes in training (Fister, 2015), and
- Detecting the over-training syndrome (Fister, Hrovat, Rauter, & Fister, 2014).

The purpose of the first application is to find some association rules in the sports training datasets obtained during athlete's training session. Usually, athletes are not aware about capacity of their body, influence of interval training on their sleeping, eating and other factors that influence on their performance. In order to help especially amateur athletes, the proposed mining the sports activities were developed. Results are presented athletes visually using glyphs (Figure 3, Figure

4). In the application, the association rule mining was implemented using the BatMiner.

The second application was devoted for detecting the over-training syndrome using association rule mining, where the Apriori was applied to real datasets created by mountain biker with mobile device. Experiments showed that this method is useful for detecting such kind of problems in sport. However, interpretation of results was still a bit weak in the application.

FUTURE RESEARCH DIRECTIONS

There is many opportunities and challenges for further research in this sports domain. Sports trackers are relatively young devices and therefore only a piece of their potentials were yet explored. On the other hand, athletes must be every year more and more fit in order to be prepared for competing on the higher level. Thus, many more parameters obtained from mobile devices during the sports sessions must be analyzed nowadays. Extracting athlete's advantages and weaknesses in dealing with various training types (intervals, long runs/rides) seems to be a promising way for further

Figure 4. An example of association rule

research besides other challenges that should be summarized as follows:

- **Finding the Proper Training Course:** The task of finding the proper training course is even more complex for sports trainers. Especially, setting up cycling course is very hard and demands many parameters by creation into account. These parameters are mostly connected with elevation, degrees of hills and even traffic conditions. In order to break this wall, data mining seems to be a promising method to find the best combination of training course.
- **Visualization:** Human beings prefer a graphic presentation against the alphanumeric presentation. In process of sports training and racing, athletes produce a lot of data that is normally presented in the alphanumeric form and usually means no special to athletes. However, a visualization of these strings enables also non-scientists a helpful view on results. One of the better solutions for visualization states on the glyph-based diagrams (Ward, 2002). Obviously, the visualization still offers many opportunities for research, e.g., visualization of segments of sports training, visualization of group of trainings, presentation of wall in performance and even virtual competitions among athletes.
- **Food Assistance:** What to eat at the proper moment is still a very peculiar question. Sports trainers and scientists had made many studies and simulations, and discovered that many factors influent on athlete's body and performance. Imagine the double ultra-triathlon (7.6 km swim, 360 km bike, 84.4km run), where an athlete's final success strongly depends on the proper food. Moreover, the proper eating is one of the most important factors in this kind of sports competition. In line with this, food prediction using data mining methods

might help athletes in choosing the proper food for long-term competitions.

- **Analysis of Rivals:** Nowadays, many data about various competitions in different disciplines are available on the Internet. Therefore, many athletes dream about analysis the advantages and weaknesses of their rivals or competitors not only in individual sports disciplines but also in team sports. On the basis of the result history, there is a possibility to achieve opponents' weaknesses using the data mining methods.

CONCLUSION

In this chapter, we presented a short overview of interesting research topic that proposes data mining in sports. Features for improving the performances of athletes, get special insight of their habits and body capacities are described. Steps of mining the sports activities are systematically showed, as well as challenges and opportunities for the future research. As a matter of fact, all these features could be integrated into the AST framework and therefore more and more specific phases of the sports training could gradually be realized by AST. Thus, the potential of the AST would be growth until abilities of the real sports trainer could finally be achieved.

S

KEY TERMS AND DEFINITIONS

Artificial Sport Trainer: Software that mimics behavior of human sport trainer in order to create a plan of sport training sessions.

Bat Miner: Algorithm for association rule mining based on bat algorithm.

Sport Tracker: Software for tracking sport activity in real-time.

Sport Training: A process built on scientific and pedagogical principles, which affects the performance of an athlete using planned and systematic training sessions.

Sport Exergames for Physical Education

Pooya Soltani

University of Porto, Portugal

João Paulo Vilas-Boas

University of Porto, Portugal

INTRODUCTION

Insufficient physical activity is one the main parameters for mortality, and obesity is a growing concern in post-industrial countries. A combination of physical exercise and healthy nutrition is essential for decreasing obesity. Active video games (exergames) are becoming popular as ways of motivating people to exercise more. However, it is not clear whether these serious games could also be used in physical education (PE) and serve as more than mere entertainment. In this chapter, we will examine existing academic literature based on the characteristics of sport exergames that are important in the domain of PE. We also provide a practical example of psycho-biophysical evaluation of a sport exergame to see how close and encouraging these games are, compared to the real sports.

BACKGROUND

PE is considered to be a crucial part of primary school curriculum around the world which include both physical and educational contents (Lindberg, Seo, & Laine, 2016). Thanks to digital technologies, new learning environments provide opportunities for skill acquisition and socializing, and researchers are now examining the role, efficacy, and opportunities that these environments provide. On the other hand, several reasons including lack of time, lack of skills of PE instructors, and lack of support might reduce the quality and quantity of PE education (Lindberg, Seo, & Laine, 2016).

Moreover, pedagogy has always tried to innovate teaching, and PE is also emerging regarding integrating technology into regular classes. One exciting area in which technology and education could merge is by using video games that include visual (and/or audio) stimulus. Video games can be applied to improve attention, executive functions, and reasoning (Neugnot-Ceroli, Gagner, & Beauchamp, 2015). They are also shown to increase several types of intelligence (e.g. visual-spatial and bodily-kinesthetic) while providing a playful-formative experience (del Moral-Pérez, Fernández-García, & Guzmán-Duque, 2015).

On the other hand, previous psychological research has linked aggression with video gaming (Anderson et al., 2010) and content analysis of video games was mainly concerned about violence and role of gender (Lee & Peng, 2006). As excessive use of technology, which also includes video gaming, is suggested to be a contributing factor in obesity, a new approach has been proposed to include active video games (exergames) that incorporate motion sensor technology and could be played using whole body movements. While gamification of regular exercise activities (e.g. GPS-based virtual reality zombie run) has been previously reported, active video games are not frequently used in the context of PE (Lindberg, Seo, & Laine, 2016), and insufficient evidence about efficacy of exergames exist within schools (Norris, Hamer, & Stamatakis, 2016). Previously, Ennis (2013) considered exergames in three categories of recreation (light to moderate intensity), public health (moderate to intensive physical activity - PA), and educational (to facilitate skills).

MAIN FOCUS OF THE ARTICLE

Motivation/Literacy to Play and Exercise

Several methods are used to increase players' motivation in sporting activities (Keegan, Harwood, Spray, & Lavalley, 2009) and game-based learning and storytelling are the primary ways to provide intrinsic motivation for learning (Laine, Nygren, Dirin, & Suk, 2016). Exergames provide a non-scary environment to develop components of mastering of fundamental movement skills (George, Rohr, & Byrne, 2016). For example, children might improve aiming and catching skills during virtual tennis without the fear of getting hit by the physical ball. In children with sensory dysfunction, exergames are used to increase their learning motivation and to make them more confident in facing various learning challenges (Chuang & Kuo, 2016). By embedding elements of nature, exergames can also provide a sense of connectedness and environmental concern, which might be important for exercising outdoor (Öhman, Öhman, & Sandell, 2016). Wittland, Brauner, and Ziefle (2015) also suggested that accepting serious games for physical fitness, is not dependent on gender, expertise, and gaming habits. However, when used with older adults, "guided hands-on" and "1-on-1" teaching methods might be used to increase their engagement when facing technology (Seides & Mitzner, 2015), because older adults need more time to master the skills necessary to play active video games (Santamaría-Guzmán, Salicetti-Fonseca, & Moncada-Jiménez, 2015). Sun (2013) evaluated the effects of exergame in primary school students and showed that PA situational interest decreases over time, but exergame intensity increases. Therefore, strategies to balance the activities should be considered during the game design phase. Many models of have been created to explore game characteristics from designers and consumers' perspectives (cf. Mildner, Stamer, & Effelsberg, 2015). Gender, age, game type, players' characteristics and personalities are motivators

for gameplay (cf. Jabbar & Felicia, 2015). For example, Shaw, Tourrel, Wunsche, & Lutteroth (2016) showed that considering personality and motivation of players in a virtual training exergame with two modes of competitive and cooperative gameplay might increase exercise, especially in competitive individuals.

Learning and Skill Acquisition

Digital games have become great tools in knowledge transfer due to fostering intrinsic motivation in players to acquire more knowledge (Mildner, Stamer, & Effelsberg, 2015). Some sports games may be used to simulate the real sports skills; for example, shooting exergames might have a positive skill transfer for increasing hitting scores (Eliöz, Vedat, Küçük, & Karakaş, 2016), and Vernadakis, Papastergiou, Zetou, & Antoniou (2015) showed that exergame-based interventions could improve object control skills in children. Moreover, players' interactions with the game and other players, affect their learning while sports exergaming (Meckbach, Gibbs, Almqvist, & Quennerstedt, 2014). Exergames might also increase PA while developing motor skills among overweight children and adolescents (do Carmo, Goncalves, Batalau, & Palmeira, 2013). Body tracking technologies have also been used as a live correcting tool for free weight exercises (Conner & Poor, 2016), and improved motor skills (balance) after exergaming was observed with higher scores in female players (Norris et al., 2016).

On the other hand, these games may not be as effective as traditional PE instructions for psychomotor development (Pedersen, Cooley, & Cruickshank, 2016). For example, virtual swimming in the air does not replicate the physical fidelity connected with moving water. A previous systematic review also showed that virtual reality applications have the ability to change behavior but have little gain in knowledge (Omaki et al., 2016). While cognitive functions are crucial for the functional autonomy, Monteiro-Junior et al. (2016) showed that a single bout of virtual real-

ity training does not have any effect on cognitive function in older adults. Johnson, Ridgers, Hul-teen, Mellecker, & Barnett (2015) also showed that short bouts of exergame playing may not influence perceived and actual ball control skill competence. Previous research also argues that when mastery is achieved, a gradual decrease in performance is expected (Adi-Japha, Karni, Parnes, Loewenschuss, & Vakil, 2016). Therefore, player balancing techniques should be used to provide an equilibrium between enjoyment and skill acquisition for players with different levels of expertise (Vicencio-Moreira, Mandryk, & Gutwin, 2015).

Competition vs. Cooperation

To gamify traditional sports, researchers and game designer are often challenged to provide a socially-enriching experience without bombarding players with game information (Choi, Oh, Edge, Kim, & Lee, 2016). Characteristics of different players should also be taken into account; for example, Staiano et al. (2012) concluded that in a group of adolescents, competitive players outperform cooperative participants on executive function test. Girls also play exergames mostly for social interaction and rather than competition, and boys play games for intrinsic reasons (O'Loughlin et al., 2012). Online cooperative exergaming can also increase social relatedness in players compared to the time when they play against a computer character (Kooiman & Sheehan, 2015).

Opinion

Previous research suggests that if PE instructors decide to use exergames in their teaching, they should justify why and how they want to apply them, and design strategies for the students to interact with exergames (Gibbs, Quennerstedt, & Larsson, 2016). For example, a meta-analytic review suggests that playing exergames can improve older adults' physical balance, balance confidence, functional mobility, executive function,

and processing speed (Zhang & Kaufman, 2015), and coaches may use these ideas to design more effective exercise programs. Exergame inclusion in PE curriculum may also provide additional tools to meet PA standards and to motivate and engage the student in practice (Rudella & Butz, 2015). On the other hand, Hulteen, Johnson, Ridgers, Mellecker, & Barnett (2015) showed that while players had correct skill performance (during table tennis, tennis, and basketball), they also had proper movement during skill assessment, which shows that presence of evaluator may affect the way participants play. According to Kooiman, Sheehan, Wesolek, & Reategui (2016), exergames should not be seen as the primary tool in PE because there are several parameters that expand the activity beyond virtual environments. Using technology in education is mostly affected by teachers' attitudes towards using technology (Albirini, 2006). While Bransford et al. (1999) talked about the four different learning environment as learner-centered, knowledge-centered, assessment centered, and community centered, it is important to decide which area benefit learning new skills in exergames more.

Characterization

In this part of the book chapter, the authors mention studies that were included in the Ph.D. thesis of the first author about characterizing a sport exergame. In the first part, the authors compared movement patterns of forty-six college students, with different performance (novice vs. experienced, and real-swimmers vs. non-swimmers) and gender. Reflective markers were placed over the skin, and the 3D position of each marker was recorded using a motion capture system. Subject played different techniques (100 m each) of a swimming exergame designed for Microsoft Xbox and Kinect (Michael Phelps: Push the Limit, 505 Games, Milan, Italy). Subjects had to stand in front of Kinect and start their gameplays by "hying" for the virtual crowd (Figure 1, Panel A). Then they had to slightly bend forward (mimicking start

Figure 1. Body position during each phase of the game

for the crawl, breaststroke, and butterfly; Figure 1, Panel B). For the backstroke technique, the start is shown in Figure 1, Panel C. Following the “Go!” command, they had to extend their back (Figure 1, Panel D) and swim according to the techniques (Figure 1, Panel E to H for crawl; Panel I for backstroke; Panel J for breaststroke, and panel K for butterfly). To start a new lap, they had to extend their arm forward (Figure 1, Panel L) and continue swimming. For terminating the race, they had to drop both arms (Figure 1, Panel M) and raise one arm immediately (Figure 1, Panel N).

The gameplay was divided into two phases of normal (with on-screen visual feedback to prevent players from playing too fast or too slow) and fast (playing without any feedback). Players’ performances were ranked from 1st to 8th. The

results showed that players who ranked better in the game (Figure 2), completed the game faster and with fewer arm cycles. By visually inspecting Figure 2, we can see that movement patterns of good performers were different that bad performers, who were mostly real-swimmers, meaning that the game does not encourage players to swim correctly. Moreover, those who had prior experience with the game had fewer arm cycles and real-swimming experience and gender did not affect biomechanical parameters.

In the second study, the authors measured and compared aerobic and anaerobic energy systems contributions and the activity profiles of participants while sport exergaming. Players were equipped with a gas analyzer to measure oxygen consumption, and blood lactate was measured us-

Figure 2. Movement patterns during swimming exergame

ing a small amount of blood from their ear lobe after each technique and following the gameplay. From these two parameters, we were able to measure the total energy expenditure (EE) during the gameplay. Players' gameplays were also filmed to measure total playing time (TPT), effective playing time (EPT), resting time (RT) and effort to rest ratio (E:R) using video analysis. Our results showed that anaerobic lactic pathway accounted for around 9% of total EE and EE was not different between performing groups. This shows that although the level of EE is lower compared to real-swimming, both energy systems should be considered when analyzing sports exergames. Heart rate (HR) was also measured during the gameplay and differences were observed between real-swimmers and non-swimmers in the first technique. This confirms that real-swimmers tend to swim correctly and exert more at the beginning of the game, but as soon as they realized the mechanisms of the game, they tend to exert less. Players were active around 57% of total time, and E:R was approximately 1.3. Our results also show that although players dedicated more time playing than resting, the changes were not different between players. Experienced players had lower TPT, EPT, and E:R compared to their novice counterparts, suggesting that experienced players learn the strategies to play the game with

lower exertion. This confirms the necessity of designing games with lower resting times (loading of the game, navigating between the menus, etc.), dedicating more time to the actual gameplay.

In the third study, the authors measured muscle activation during sport gaming. Surface electromyography electrodes were placed over Biceps Brachii, Triceps Brachii, Latissimus Dorsi, Upper Trapezius, and Erector Spinae muscles. These muscles were chosen as they are frequently activated during swimming or were relevant because of the game itself. Maximum voluntary isometric contraction (MVIC) of each of the muscle was also measured to normalize the activation in percentages. Our results showed that muscle activation ranged from 5 to 95% MVIC, and differed between normal and fast swimming for all techniques. Muscular coordination was also investigated using biomechanics and observed that when participant plays faster, they complete different stages of the game faster, which results in higher stress some of the muscles more. Measuring muscle activation is important because it can show if players with greater experience, exert and engage less or not. While challenges in sedentary games are usually controlled by adjusting the complexity of mental tasks, employing in-game physical challenges can be unique characteristics of exergame design

and muscle activation evaluation can provide guidelines to make sports exergames closer to real activities. Such evaluations can also address the Concerns regarding long-time computer/video game use, repetitive movements, and musculoskeletal disorders, such as neck and shoulder pain. Moreover, although sports exergames may not produce as much muscle activation as the real activity, such activities might still benefit participants to develop muscular endurance, especially when participation in real sport is not possible or practical due to disability, fear, or injury.

In the last study, the authors evaluated the game experience, usability, and enjoyment during sport exergaming to see if they affect future participation if PA and/or real sport. Enjoyment can both predict and be an outcome of PA participation and is one of the reasons why people play video games. System usability scale (SUS) is a measurement of learning, control, and understanding a game, and higher SUS grade means easier interaction between human, different games and menus, and various controllers and gaming platforms. User experience (UX) deals with consumers' dynamic perceptions and responses of products and systems and is an important factor for game design and positioning of the problems. For measuring enjoyment, a short version of physical activity enjoyment scale (PACES) questionnaire with two additional questions was used to measure future intentions of participation in physical activity and real swimming. Game usability was measured by System Usability Scale and playability aspects using Game Experience Questionnaire. Our results showed that Female players with real swimming and exergame experience enjoyed the game more. Usability score was around 75 which is considered as good with high acceptability. PA intentions did not change within performing groups, but swimming intentions were increased for all players. A possible explanation might be that future PA intentions of those who frequently exercise, may

not be affected by playing exergames. Another explanation might be that those who do not exercise regularly, may think that the health benefits attained through exergaming are enough, and there is no need for further PA participation. It might be possible that novelty and entertainment elements of swimming exergame, played a role in influencing players' attitudes towards real swimming intention.

FUTURE RESEARCH DIRECTIONS

In our research, most of the players had sports science background and were physically active. This might have influenced the way they were interacting with the game. The presence of the researchers themselves might have affected players' performance to play differently. It might be possible that novelty and entertainment elements of swimming exergame, played a role in influencing players' attitudes towards real swimming intention and therefore, longitudinal studies should be conducted to check the changes in intentions in the long run.

CONCLUSION

In general, our data suggest that better performance inside the game does not necessarily mean better performance in real swimming. The motion capture sensor is also not capable of capturing delicate movements of swimming, and it does not encourage players to swim correctly. Therefore, the game may not be used as a training tool for real swimming and may only be used as a motivational tool for teaching basic movements of swimming (e.g. coordination of the upper limbs). While we do not deny the possible role of video games in PE settings, we believe that there is still a long way to use sport exergames in the PE.

KEY TERMS AND DEFINITIONS

Exergame: A combination of “exercise” and “game” is a term used for video games that are also a form of exercise.

Game User Research: It focuses on players’ behavior via techniques such as playtesting, analytics, expert analysis, and others.

Game-Based Learning: A type of game play that has defined learning outcomes.

Skill Acquisition: A specific form of learning as the representation of information in memory concerning some environmental or cognitive event.

INTRODUCTION

Recent advancement of information and communication technology on mobile communication has changed the way people communicate, interact, and carry out their daily activities. The new era of wireless multimedia communication with smartphones has replaced old cell phones. Major players in the cell phone industry such as Nokia has lost their market shares and new players such as Apple (iPhones) and Samsung (Android phones) dominate the market.

Smartphones are very handy. Although they cannot replace all desktop or laptop's functionalities, they can be carried around conveniently as multipurpose devices. There are a myriad of applications (apps) that can run on smartphones and thousands of new apps are created everyday. The main advantage of smartphones is its ability to connect to the Internet from anywhere, enabling their users to have a complete Internet experience, stay in touch with their families, friends and colleagues, checking emails, making reservations, checking the traffic condition and so forth. Travelling with a smartphone is very helpful. With a digital map app, finding a place is much simpler in comparison to conventional methods. The map can also enlighten us to the location of ATM machines, restaurants, gas stations and others.

While traveling, a person with a smartphone can easily navigate his/her way through unfamiliar routes and keep in touch with family and friends through social networking such as sharing photos with Instagram or video chatting with Skype.

The heart of a cell phone or smartphone is an operating system (OS), a system that controls and manages all resources. As companies that produce cell phones rely on conventional innovation, where they rely on vertically integrated research to foster new technologies (innovations) for competitive advantage, most OSs for cell phones are proprietaries. Consequently an attempt to introduce open source OS in cell phones such as mobile Linux was not very successful since companies producing cell phones need to adopt Open Innovation for their core technology. According to Chesbrough, Vanhaverbeke & West (2006) "Open Innovation is the use of purposive inflows and outflows of knowledge to accelerate internal innovation, and expand the markets for external use of innovation, respectively." This means companies can adopt external technology such as OSS in advancing their technologies and markets.

Open Source Software (OSS) is free software that provides its users with freedom to use, replicate, modify, and distribute for any purpose. Unlike proprietary software where the executable code is commercially distributed under a copyright

DOI: 10.4018/978-1-5225-2255-3.ch641

law, the source code of OSS is available and a user has freedom to modify the source code, creating another version or an extended version of the software.

OSS proponents often state that it offers significant benefits when compared to typical commercial or proprietary software. Commercial software typically favours visible features (marketing advantage) over harder-to measure qualities such as stability, security and similar less glamorous attributes. In short, although OSS visible features may not be as good as the commercial one, OSS quality is normally high. OSS developers are evidently motivated to focus more on quality rather than visible features. For many developers, peer review and acclaim are important. They definitely prefer to build software admired by their peers where clean design, reliability and maintainability, with adherence to standards is highly regarded. "The Open Source community attracts very bright, very motivated developers, who although frequently unpaid, are often very disciplined" (Peeling & Satchell, 2001).

Nowadays most smartphone vendors have adopted OSS in their Open Innovation strategy to expand their business. Open source OS for smartphones such as Android have been widely accepted and in fact has been a dominant OS for smartphones since a few years ago. Interestingly, some smartphone vendors that used proprietary OS, developed and intend to use open source OS such as Maemo and MeeGo (Nokia), and webOS (Palm). Tizen, an alternative open source OS, has been developed by Samsung, Intel and Linux Foundation. Some old OSS players have released open source OS for smartphones such as Firefox OS from Mozilla and Ubuntu Touch from Canonical.

This chapter discusses the Open Innovation and adoption of OSS in smartphone industry. The development of OSS and its use in smartphones will be presented. The competition between proprietary and OSS operating system for smartphones will be discussed as platforms or operation system that shape the smartphone industry. Future direction will be presented in the last part of this chapter.

The next section will present the background followed by a discussion on the development of OSS and smartphone platforms in Section 3. Section 4 will discuss the impact of OSS on smartphone industry. Additionally, Section 5 will be on the future direction and the last section concludes this topic.

BACKGROUND

Open Innovation is a concept introduced by Chesbrough (2003) in which a company use both internal and external knowledge to create values. Chesbrough (2003) defines Open Innovation as "A paradigm that assumes that firms can and should use external ideas as well as internal ideas, and internal and external paths to market, as the firms look to advance their technology." Open Innovation can be contrasted with closed innovation where a company relies on vertically integrated research to foster new technologies or innovations and keeps them secret or strictly protected using intellectual property (IP), meaning that no other companies can use them.

Open Innovation and OSS are two different concepts sharing some similarities as said by Chesbrough (2006): "Open Innovation is sometimes conflated with open source methodologies for software development. There are some concepts that are shared between the two, such as the idea of greater external sources to create values." Technically OSS can be considered as a kind of Open Innovation where a company outsource software needed to the community (open source community) or alternatively a company can contribute its software to the community after turning it to open source software.

Interestingly, though the benefits of OSS are obvious, OSS has not yet been widely used and accepted in the PC world. Despite some of the hindrance factors mentioned above, some OSS gained wider acceptance, such as Linux, Apache, Sendmail, PHP, MySQL, and Firefox. Linux for example is a very reliable and powerful operat-

ing system that can be run on less powerful PCs. Remarkably a well-known website, Google, has used Linux servers since its inception. According to Sergey Brin, who was one of Google founders, said that they chose to use Linux because it is the most cost effective solution (Schumaker, 2000).

OSS is always strong in the platform level. This strength prevails in the smartphone world. Smartphones integrate cell phones and personal digital assistant (PDA) technologies. Cell phones with some features of smartphones were introduced by the end of 90s or early 2000 such as the Nokia 9000 Communicator and BlackBerry. In fact, Ericson used the word smartphone for its GS88 in 1997 (Yousuf, 2013). However, the major breakthrough was the introduction of iPhone by Apple in 2007 with its proprietary OS, iOS. The mobile phone market was shaken by the introduction of iPhone. By 2008, iPhone with iOS dominated the smartphone market with market share close to 80%. The success of iPhone was followed by the introduction of Android by Google in 2008. Domination of iOS was challenged by Android after one year of its introduction. Within a few years, smartphone OS is dominated by Android, an open source OS, with market share of 79.3% in the second quarter of 2013, while iOS is losing its market share, 13.2% in the second quarter of 2013 (Clover, 2013).

LITERATURE REVIEWS

According to Chesbrough (2011), there are two facets to Open Innovation, outside in and inside out. Outside in commonly occurs in Open Innovation. It is when a company imports knowledge, ideas or technologies from external sources and integrate them into the company innovation process. Meanwhile, the less commonly occurring inside out Open Innovation is when a company exports underutilized knowledge, ideas or technologies to be incorporated into other companies' innovation processes.

OSS is a manifestation of Open Innovation in software development (Liu, 2009). Both outside in and inside out approaches are utilized by companies that adopted OSS as part of their innovation strategy. Android is a notable example of outside in Open Innovation adopted by smartphone manufacturers.

The history of OSS can be traced back to early development of large-scale commercial computer in the 1950s and 1960s where software was free and came with source code. The source code can be modified and recompiled to improve the software. At this time the software was not considered as a revenue generator, instead, software was a necessary ingredient to make hardware work and provide useful functionalities or solutions so that people are encouraged to buy expensive hardware or mainframes.

The term Free Software (FS) has been put in place by Richard Stallman (Stallman, 2010). He is the one who established GNU Project and Free Software Foundation and introduced GNU General Public License (GNU GPL). This license guarantees that software under it is free. The term open source software is used instead of free software to embrace the business world (Perens, 1999).

The open source movement shares the basic principles of Stallman's free software movement. As Stallman (2010) said, "free software" and "open source" describe the same category of software, more or less, but say different things about the software, and about values. He further said, "The Free Software Movement and Open Source Movement are two political parties in the same community."

The open source movement has taken a different path from the free software movement to promote the idea of free software. Notable persons in Open Source Movement such as Eric Raymond, Bruce Preens, Tim O'Reilly and others are concerned about the negative connotations of the previously used name Free Software Foundation (DiBona, Ockman, & Stone, 1999), a term considered to be non-business friendly. Thus, they

agreed to promote the idea with a new term, open source software. The new term attracted a lot of support from hacker culture (Raymond, 1998) as well as software companies such as Netscape, Sun Microsystems, and IBM.

The rapid development of OSS has taken place since the 1990s. In the early 1990s, for instance, Net/2, or 386BSD, a UNIX based operating system that was free from AT & T copyrighted code was introduced. Hence, 386BSD was a completely free operating system. The 386BSD was the root of other BSD-based operating systems such as OpenBSD, FreeBSD and NetBSD.

Another milestone in OSS is Linux or to be precise, GNU/Linux. Linus Torvalds originally developed Linux when he created the Linux kernel based on Minix, a UNIX-like small operating system that could run on a PC, designed by Tanenbaum (2006) for teaching purposes. Torvalds and GNU project team collaborated and integrated high-level functions produced by GNU with Torvalds's kernel to form a new operating system called Linux. Linux was released under the GNU GPL license (Towle, Keppler, & McFarland, 2004).

Currently, there are thousands of high-quality OSS which addresses many solutions for different areas. The OSS eventually enjoyed wide acceptance with the support from giant IT companies such as IBM, Hewlett-Packard, Sun Microsystems, and Google. Many government organizations have committed to adopt OSS (van Wendel de Joode, Lin, & David, 2006).

OSS development is different from the traditional software development, which relies on central control that follows a strict schedule. Many developers, based on trust and cooperation or collaboration, develop OSS. Raymond (2001) in his famous work differentiate traditional software and OSS development as "The Cathedral and The Bazaar."

Linus Torvalds introduced the OSS development model when he released the source code of the Linux kernel for Intel 386 machines on the Minix community in the Internet (comp.os.minix)

and was requesting for collaboration in order to further develop it. He received many responses and many programmers contributed code to the project. Later on, in January 1991 the Linux community was formed by launching a news group called alt.os.linux, which became comp.os.linux in March 1992 (Torvalds, 1999).

Collaboration among programmers in the Linux community with the leadership of Torvalds has made Linux a strong and stable operating system in a flash. Raymond (2001) called Torvalds's development model as the bazaar development model.

Prior to smartphones, all cell phones operating systems were proprietary. Until 2009, Symbian (OS used by Nokia cell phones) was a dominant OS followed by RIM BlackBerry OS (Gartner, 2007). Perhaps the only OSS component on cell phones was Java ME, a platform to run applications.

Research in Motion (RIM) introduced BlackBerry in 1999 with an innovative feature, which was not supported by other phones. BlackBerry phones have the capability to send and receive emails or messages through BlackBerry Messenger (BBM) supported by a mini QWERTY keyboard that simplifies typing messages (Hall & Anderson, 2009). A significant breakthrough in mobile phone industry is the introduction of iPhone in 2007. The iPhone OS, iOS, is a completely proprietary system. After its introduction, iPhone enjoyed wide acceptance from end users and quickly held a significant market share in 2008 and iOS became a very popular OS.

Google entered the smartphone market by introducing Android, an OSS of Linux-based operating system, in 2008. Many major smartphones vendors such as Samsung, HTC, and LG adopted Android as the OSS in their products. In addition, the growth of apps that can work on Android staggered, consequently in a very short time Android challenged iOS, took over the market, and became dominant in 2011. Nokia, the dominant player in cell phones keep losing its market shares since the introduction of iOS and then lose further after the wide acceptance of Android.

The popularity of open source OS for smartphones has attracted several vendors such as Nokia, Samsung, and Palm/HP to develop open source OSs. Nokia bought Symbian and turned it to open source OS and subsequently developed Maemo (Maemo.org) and MeeGo (Kenney & Pon, 2011; Morrison, 2013) but lost faith to both of them. Samsung has developed Bada (Bada.com) which has been absorbed by the new open source OS project, Tizen (Tizen.org). Palm/HP developed webOS, which was acquired by LG in February 2013 (Ion, 2013).

There are some new OSS projects on operating systems for smartphones such as Firefox OS (www.mozilla.org/en-US/firefox/os/), Sailfish OS (sailfishos.org) and Ubuntu Touch (www.ubuntu.com/phone), and Jolla (Jolla.com).

WHY OSS PREVAIL IN SMARTPHONES

OSS in the Computer World

OSS has been around for more than two decades. The strength of OSS has been recognized, especially in the platform level. Several researches have been conducted to compare the reliability of OSS as compared to proprietary counterparts and data indicated that OSS is more reliable (Forrester & Miller, 2000; Miller et al., 1995; Miller, Cooksey, & Moore, 2006).

So far, majority of OSS influence is on the platform level, unable to shake the domination of Microsoft on the consumer level (PCs). According to Cosovanu (2006), there are four main reasons as to why OSS is still not widely used. Firstly, cheap pirated copies of proprietary software are widely available. Secondly, proprietary software, especially Microsoft operating system and its main application suite have achieved overwhelming market share, which is over 90% among the PC users. Thirdly, most new PCs are pre-installed with Microsoft operating system and its office suite. Fourthly, there is a conservative bias of many busi-

nesses and state bureaucracies toward proprietary software, especially Microsoft's products.

However, a report from Forrester (2007) indicated a growing adoption of OSS across all geographies and industries. The roles of major vendors (investment, contributions, participation) in this expansion are quite significant. Based on the survey conducted by Forrester, many companies in North America and Europe has trusted OSS in their mission-critical applications although the majority of the companies surveyed used OSS in non-mission-critical applications, application infrastructure (application server, portal server, web server), server operating system and development tools.

The Forrester report further reveals that it is not the cost of acquiring (no license cost for OSS) that appeals to companies, however, the three attributes namely, support for open standards, the ability to use without restriction, and not being locked in to a single vendor. Figure 1 shows the degree of importance of OSS attributes.

It is interesting to see the change of attitudes of the business world, especially large corporations, toward OSS. At the early stage of OSS development, large companies were suspicious. After sometime, they accept the phenomena of OSS and finally indicate their favorability by adopting OSS or Open Innovation in general as part of their business strategy (Liu, 2009).

OSS in the Smartphone World

Prior to the introduction of smartphones, few players dominated the cell phone industry. The top five vendors in 2006 were Nokia, Motorola, Samsung, Sony Ericson, and LG with market shares of 36.2 percent, 21.5 percent, 11.3 percent, 9 percent, and 6.3 percent respectively and the figures did not change much from the previous year (Gartner, 2007). None of these vendors has OSS in their core products other than the Java platform (Java ME) to run Java-based applications (applets).

In 2009, two years after the introduction of iOS and one year after the introduction of Android,

Figure 1. Preference of Attributes of Open Source Software (courtesy of Forrester, 2007)

the smartphone industry, especially Samsung and HTC, responded positively by embracing Android as the operating system of their smartphones. Similarly, application developers responded with a myriad of apps for Android within a short time. To see the effects of OSS (in this case Android), we have to look at the market shares of major operation systems for smartphones in Table 1 and Figure 2 shows the trend graphically. Note that Android is the only open source OS in Table 1. By 2011 the smartphones world is dominated by two OS, Android and iOS, an increasing trend for Android and a decreasing trend for iOS except for quarter 2 (Q2) in 2015.

According to Yu (2013) a smartphone OS market share has a correlation with its mobile apps developer community as there is a relationship between smartphones, OS and apps. This indicates that Open Innovation prevails in the smartphone industry. Android enjoys strong support from its developer community; consequently, the number of apps is growing fast. The role of apps in attracting users of smartphones is important as they expand the functionality of the smartphones.

Figure 3. shows the growth of apps in Sourceforge (sourceforge.net), a cloud for developing applications, including mobile apps. If we explore the growth of apps in Sourceforge, the most popu-

Table 1. Smartphone operating systems market share (in percent)

Operating System	2009	2010 (Q4)	2011(Q4)	2012(Q4)	2013(Q2)	2014(Q2)	2015(Q2)
Symbian	44.9	32.3	11.7	1.2			
iOS	14.4	15.8	23.8	20.9	12.9	11.6	13.9
Android	3.9	30.5	50.9	69.7	79.8	84.8	82.8

Others	3.8	6.1	2.8	1.6	1.2	0.7	0.4

Source: various reports from Gartner and IDC

Figure 2. The growth of market share of major mobile OS

lar and the largest OSS community developer's repository, we can infer that Android has been enjoying a strong support from OSS community starting from its conception.

It cannot be denied that Apple, through iPhone and iOS, created a breakthrough in mobile device technology. iPhone integrates telephony, the Internet and a myriad of applications from third parties, making iPhone outperform other mobile phones. The seamless Internet connection with

full browser capability has let end users experience Internet value network ubiquitously (Kenney & Pon, 2011). In addition, AppStore and iTunes have created an innovative ecosystem containing end users, third-party application developers, and Apple Inc. The openness of iOS to third-party developers further increase the value of iPhone (iPod and iPad), and iOS as innovations from the third-party applications are embraced, creating symbiotic mutualism between Apple and its third-

Figure 3. The growth of apps of several mobile OS in Sourceforge (Source: Yu, 2013)

party developers. Although iOS is a close source software, proprietary and exclusively designed for Apple's products, Apple also adopts Open Innovation strategy to multiply the value of its products in a controlled manner.

The exclusiveness of Apple for its products (Apple will not license iOS to any smartphone manufacturer) has made the introduction of Android, an open source OS, warmly welcomed by smartphone manufacturers such as HTC and Samsung, subsequently producing smartphones with comparable capabilities to iPhone.

Google, the big player in the Internet, decision to enter smartphone market is interesting. Google did not have experience in any mobile platform. Therefore the best way is to pick a good open source OS, adopting fully the Open Innovation approach to secure its position as the top Internet player since smartphones are ubiquitous client machines to access the Internet. Google bought Android Inc, a company co-founded by Andy Rubin that develops a Linux-based operating system for touch screen mobile devices and appointed Andy Rubin as the director of mobile platforms at Google (Beavis, 2008). With the cooperation of Open Handset Alliance (OHA), which includes Samsung, HTC, Sony, and LG, Google unveiled Android on November 5, 2007 and within one year (October 22, 2008), the first Android smartphone, HTC Dream, released (Perez, 2008).

Google does not use Android as a moneymaker directly as Android was released as an OSS and smartphones manufacturers do not need to pay a license fee to use Android as the platform for their smartphones. Google expects Android to attract people to use its Internet services, creating more traffic to get more revenue from the traffic through advertisements and data usage. Consequently, Google spent considerable effort to promote Android, especially to application developers, to create a similar ecosystem to iPhone (Kenney & Pon, 2011). Figure 2 shows the response from application developers that use Sourceforge as their development repository. In addition, the expansion number of apps developed

for Android in several well-known repositories such as Sourceforge, Google Code, and Git Hub is surely highly related to the expansion of available apps in Google Play, which in turn help Google strengthening its Android ecosystem.

FUTURE RESEARCH DIRECTIONS

Android is now a dominant OS for smartphones. However, Google does not acquire direct financial benefit from the popularity of Android. Perhaps the acquisition of Motorola Mobility in May 2012 is an attempt to take direct benefit from Android, but failed. It is interesting to study the reason as to why Motorola Mobility was acquired. One of the reason revealed by Google that the intention in acquiring Motorola Mobility is to gain control on patents owned by Motorola Mobility to protect Android's ecosystem. However, the ownership was not long, Google sold Motorola Mobility to Lenovo in January 2014. On the other side, Google has Chrome OS a product of the Chromium OS Project, an OSS project aimed to produce a web-based operating system. It is not clear how Google treat Android if Chrome OS successfully gain market, when Google has full control on the latter. Does Google want to take advantage of the advancement of mobile computing with a lightweight OS (Chrome OS)?

As a first mover in touch screen mobile devices (smartphones and tablets) Apple with its strong brand and innovative products has always secured its market, although its market share has decreased. In the tablet market, iPad is still leading the market with a market share of 55% (October 2013). Mobile device products with proprietary operating systems keep losing the market such as Windows OS and BlackBerry. The survival strategy of Nokia by taking a proprietary OS (Windows OS) is not clear. Microsoft fully absorbed Nokia in April 2014. The big question is: can Nokia, under Microsoft, gain significant market share in the future?

There are several open source projects working on operating systems for smart mobile devices.

Among others are Firefox OS, Sailfish OS, Tizen and Ubuntu Touch. We do not know the fate of these OSs in the future. However, they are alternative OSs that may challenge the dominant duo, Android and iOS. Perhaps the new open source OS can tap the emerging markets for lower-end mobile devices. As discussed previously, the key for a mobile OS to success in the market is strong support from application developers and creating an ecosystem to attract application developers to contribute their innovation.

Nowadays people live with their smartphones, but unfortunately, information stored in their smartphones is well protected. A growing concern from end users on security and privacy issues need to be addressed. Mobile network is far from secure and the same goes to the Internet. Therefore, research are needed to advance security and privacy issues in smart mobile devices.

CONCLUSION

Open Innovation prevails in smartphone industry. OSS is a kind of Open Innovation in software development majorly utilized by smartphone manufactures as part of their innovation strategy.

OSS is a free software that provide users the freedom to use, replicate, modify, and distribute for any purpose. In the early stages of OSS, the business world, especially large corporations were not interested and some were suspicious of OSS. Strong support from programmers and quality software produced through OSS development methodology have changed the attitude of the business world to favor, support and embrace OSS including many big computer corporations such as IBM, Oracle and Google.

Apple made a breakthrough in consumer mobile devices by introducing touch screen mobile phone (iPhone) and tablet (iPad) equipped with powerful but easy to use operating systems in 2007 with its proprietary OS, iOS. The mobile phone market was shaken by the introduction of iPhone, and within one year, the smartphone

market was dominated by iPhone. Google, a giant Internet player entered the smartphone market by introducing Android, an OSS of Linux-based operating system in 2008. Supported by many smartphone manufacturers, application developers and open source communities, Android quickly grabbed a significant market share after one year of its introduction and continues to grow until it became dominant after three years of its introduction.

One of the important key success factors of any smartphone platform is innovation created from the platform and applications developed for the platform that greatly attracts end users. Both Android and iOS have successfully created good ecosystems to help them grow. However, the power of Open Innovation in open source software to create such ecosystem is stronger than proprietary software, possibly one of the reason for the widening gap between Android and iOS market shares.

The popularity of open source OS for smartphones has attracted several vendors such as Nokia, Samsung, and Palm/HP to develop open source OSs. New players such as Mozilla (Firefox OS) and Canonical (Ubuntu Touch) are trying to penetrate the market. However, their success depends on their ability to create a good ecosystem to grow and challenge the market leader.

KEY TERMS AND DEFINITIONS

Android: Android is an open source Linux-based operating system designed for touchscreen smart mobile devices (smartphones and tablet computers). Google and Open Handset Alliance (a consortium of hardware, software, and telecommunication companies such as Samsung, HTC, Qualcomm, and T-Mobile) use Android.

Free Software (FS): FS has been introduced by Richard Stallman to denote users the freedom to execute it for any purpose, replicate, modify and redistribute copies of the original or modified software. “Free” in the free software refers to freedom, not refer to price. Free software is under copyleft, a distribution concept to make sure that software under this term is always free.

iOS: iOS is proprietary operating system designed for dedicated touchscreen mobile devices developed by Apple such iPhone, iPad and iPod touch.

Open Innovation: Open Innovation is the use of purposive inflows and outflows of knowledge to accelerate internal innovation, and expand the markets for external use of innovation.

Open Source Software (OSS): Open source software share the same principle of FS. According to Richard Stallman 'free software' and 'open source' describe the same category of software, more or less, but say different things about the software, and about values. He further said, "The Free Software Movement and Open

Source Movement are two political parties in the same community".

Proprietary Software: Proprietary software is a commercial software where the core is kept secret by the developer, users of the software have to pay license fee and do not have the right to lend the software to their colleagues, let alone modify.

Smartphone: A smartphone is a mobile phone that let one not only make telephone calls, send short messages, but also surf the Internet, play games, listen to music, watch movies and other capabilities normally provided by computers such as writing and editing documents, sending and receiving emails and run a myriad of available apps.

Assessing Computer–Aided Design Skills

Yi Lin Wong

The Hong Kong Polytechnic University, Hong Kong

Kin Wai Michael Siu

The Hong Kong Polytechnic University, Hong Kong

INTRODUCTION

Computer-aided design (CAD) is the use of computer technology to aid design. It is often referred to the use of computer software to draw two- or three-dimensional drawings or models. It improves the quality of drawings and models, makes the communication in design processes more effective, and increase the productivity of the entire process. Most schools and universities would offer CAD courses for students in design or engineering disciplines and subjects.

Assessing students' knowledge and skills of using CAD computer software is thus inevitable. However, the assessment of CAD is often problematic. Computers are not always available because of the facilities arrangement and administrative issues in schools or universities. It is ineffective and difficult to arrange computers for a large group of students in an examination. The number of CAD software licenses may also be limited, and students are unable to use the software at the same time. Grouping students in different time slots to take the examination may be an eclectic way to solve the issue; however, the tutor or the lecturer would have to develop several sets of questions for the students. The examination in this case also loses its authenticity, as students are able to guess the questions based on the comments of students who took the exam in an earlier time slot. In addition, using particular software in CAD examination can only assess students' familiarity towards the software but not the general knowledge of CAD.

The issues of computer facilities and software license and the limitations of computer-based

examination made CAD assessment difficult. Taking references from some computer programming subjects, it is believed that using paper-and-pencil method is a choice to solve this problem. However, the scope of paper-and-pencil questions is limited, as the questions appeared in the examination can only comprise the most common functions in various CAD software.

This chapter discusses the issue through examining and reviewing existing CAD examination questions in Hong Kong. Based on the review, limitations of the current assessment are highlighted. It is argued that the existing method is inconsistent with the problem solving nature of the software and is unable to assess students with high ability and advanced drawing skills. Recommendation and improvement directions are suggested in the chapter to optimize the quality of assessment. Other subjects which also involve assessment of computer skills and design may also benefit from the recommendations.

BACKGROUND

The term computer-aided design appeared in the late 1960s (Abbas, 1976). Since then, many different disciplines of engineering applied CAD, and the industries also needed staff possessing this kind of skills to make their designs and products to catch up with the trend. Educational and academic institutes had also started to introduce CAD courses to their students. Some institutes had offered CAD course as an elective subject, or combined the knowledge of CAD in other

existing subjects related to engineering design. Specialized and short courses of CAD were very popular in various engineering disciplines and increasingly in design disciplines. As students in design disciplines had not got any technical training, they encountered difficulties in using the computer software, and sometimes they could not get what they wanted through CAD. Apparently, this discrepancy is getting smaller over the years, and now students without technical background are able to use computer software to assist design effortlessly. This is primary due to the popularization of computer technology in the last few decades.

Nowadays, CAD has been extending its application in other disciplines such as mathematics, music and geography. Various kinds of CAD software have been developed to attract the attention of the industries and the academia. The software may possess similar function but different layouts and orientations to provide choices for different needs of the customers. However, due to limitation in resource and time in universities, tutors and lecturers can only teach the selected software based on the actual needs. Students have to explore other software by themselves. Some secondary school teachers have also noticed the needs and started to contact the software companies to buy school license for the computers in the computer laboratories. They have started to rearrange the curriculum and put CAD knowledge and abilities as one of the learning outcomes.

Teaching CAD Software

One of the most effective ways of teaching CAD is to demonstrate the drawing procedures of a particular drawing or model step by step. Teacher can first show the finished drawings and ask students to follow the teacher while the teacher draws on the computer. Teacher will be able to help students and solve students' problems while teaching the steps. At the end of the lesson, all students will be able to finish the same drawings. Through the drawing process, students can learn

different functions of the CAD software. Teacher can also allow students to decide how they use a particular function in the drawings, e.g., whether the function should be applied on this line or the other line. In this way, different students can have different drawings in the end of the lessons. However, this is only applicable to students with higher learning ability. Sometimes the CAD skills learnt are transferable, and they can be applied in using other CAD software. There are many other methods to teach CAD skills. For example, teachers can use problem-based projects to facilitate students learning CAD software.

Learning CAD Software

Prior to learning CAD software, students need to possess basic computer knowledge. They should be very familiar with the operation system of their computer, e.g., Windows and Macintosh, before they can create and generate drawings and models in their mind through the CAD software. They also need to learn the basic shapes that comprise a drawing and analyze the drawings they wanted to create. They need to possess the cognitive ability to manipulate the drawings in the mind before working on the computer. The prior knowledge is essential to facilitate students to learn the functions of the CAD software. Once students are familiar to the functions and the working procedures of the software, they will be able to draw any drawings or make any models they need for their designs. Students will be able to produce neat and clear drawings and present their design ideas more effectively. Some students can make use of the features of the CAD software to design while drawing. The convenience and the effectiveness of CAD software also facilitate the idea generation in design processes. Chester (2007) had made a comprehensive discussion about CAD expertise. He identified two kinds of knowledge: command and strategic knowledge. Command knowledge is the knowledge of the commands and the drawing procedures. Strategic knowledge is the alternate method of finishing a specific drawing or task.

It can be argued that the strategic knowledge is essential in transferring the command knowledge in other CAD software.

Assessment of CAD Learning

Currently, the assessment of the CAD courses often focuses on the application. In general, there are two kinds of formal and formative assessment: computer approach and paper-and-pencil approach.

In computer approach, the typical assessment method is to request students to perform a series of tasks by using designated computer software in a given period of time. The computer software is often the one they used in lessons. When this approach is adopted, resources, time and question setting-up techniques become essential. In order to have a fair examination, the best way is to allow all students in a cohort to sit in the same examination at the same time doing the same questions. However, due to the limitation of computer and software resources, it is hardly possible. Another possible option is to assign students into different groups and take the examination at different time slots doing different set of questions; yet, this requires advanced question setting-up techniques to guarantee the different sets are of the same level of difficulties. In order to solve these issues in formal and formative assessment, paper-and-pencil approach may be one of the most feasible solutions.

In paper-and-pencil approach, students have to use verbal and graphical methods to describe the procedures needed to draw a particular drawing assigned in the examination question. This is the most convenient method, as the arrangement is the same as in the examination of other common subjects. Students are assigned to sit in a room, and what they need to do is to write their answers on the answer sheets.

Research About CAD

Unsurprisingly, educational researchers and researchers concerning the development of engi-

neering and design also start to pay attention to the CAD education. For instance, Gül (2014) studied the instructional methods used in CAD courses of interior architecture education. The four common instructional methods used in CAD courses identified by Dönmez (2013), namely theory based, invention based, searches and analyze based, and collaborative learning based instruction methods, were used to analyze a CAD course in a university of Turkey. Ye et al. (2004) investigated the contents taught in a CAD curriculum and found that the contents taught were not inadequate. Field (2004) discussed what kinds of knowledge are essential to support CAD training and education. Spatial reasoning, solid geometry, mathematics, and exercises in modular design within a team environment should be included. He argued that the CAD education should progress in line with the development of CAD technologies. Rossignac (2004) found that the typical way of teaching CAD was unable to improve students' ability of using CAD and advocated "education-driven research" in CAD.

Rossignac (2004) was not the only researchers who had found difficulties in teaching CAD. According to Piegl (2005), the CAD education still encounters several issues in its development. It lacks comprehensive textbooks for specialized CAD such as rapid prototyping and teachings aids for general purposes. There is no officially recognized CAD curriculum, and this has hindered CAD from globalization. There is also no unique international CAD society to gather all the experts. Up to day, there is no specific journal to support further research and conference about CAD education. The current inattention to CAD education has neglected the learning and teaching aspect of CAD knowledge, and soon universities would become "research university" with secondary focus on learning and teaching (Piegl, 2005).

All the issues and the researches about CAD education mentioned above are related to learning and teaching. None of them concerns the assessment of CAD education. In fact, assessment is important to evaluate the achievement of

students and the success of a curriculum (Morris, 1996). Through assessing students' learning outcome and performance, lecturers and tutors can revise the teaching methods applied and the contents selected for the curriculum. However, currently researches and discussions about assessment of CAD education are lacking. Data about how CAD beginners learn the computer software are also inadequate (Hamade, Artail, & Jaber, 2007).

Hamade et al.'s (2007) research study used time to assess students' performance. They measured the time that students used to draw an assigned model and correlated it with the number of the features selected by the students. This may provide a sounding empirical data about students' performance in CAD; however, this is not applicable and practical in normal classrooms or examinations where in-depth data collection and analysis are not considered.

DIFFICULTIES OF ASSESSING CAD KNOWLEDGE

Apparently, assessing CAD knowledge effectively is not as easy as it seems. Perhaps CAD knowledge teaching at the tertiary level is more flexible and independent that formal assessment is not required. However, when it comes to the context of secondary school level, the issue is more restricted, and it is necessary to develop a formal and formative assessment method to evaluate students' learning outcome in a one-off manner. The following sections of the chapter study the issues and difficulties of CAD assessment through an example of the paper-and-pencil approach that assesses students' 3D CAD drawing skills. Through the investigation and discussion, the difficulties of assessing CAD knowledge are identified. Also, the discussion is able to provide insight to modify and prove the current way of CAD assessment.

An Example of the CAD Assessment

S

Public examination about CAD is considered as a reliable example of paper-and-pencil approach for investigation. The subject of Design and Applied Technology (DAT) in the Hong Kong Diploma of Secondary Education (DSE) includes CAD as one of the elective modules in its curriculum. The elective module is named 'Visualisation and CAD Modelling'. In this module, students have to learn prototyping and drawing (both 2D and 3D) by using computers. However, most of the public examinations focus heavily on 3D drawings, and 3D drawing technique is often assessed. This type of questions is also very popular in the recent years, and it is welcomed by most students. Taking the 2014 DSE examination as an example, one of the questions asked students to 'draw' a fork end. The question is divided into two parts:

1. Sketch the primitive solid models required for constructing the 3D CAD model of the 'fork end' shown in Figure 15. (5 marks)
2. Using 'Boolean operations' and the primitive solid models from (a), draw a series of annotated sketches to show the major steps required in constructing the 3D CAD model of the 'fork end'. (20 marks) (extracted from Hong Kong Examinations and Assessment Authority, 2014)

This is a typical way of assessing computer skills by paper-and-pencil approach. Students have to draw two primitive solid models on paper, and use Boolean operations (which are included in the curriculum) to illustrate how they could work out the form they need. For instance, students have to draw a cube and a tube on the answer sheet provided. They then need to use the cube and the tube to perform union, difference or intersection function so that the desired object, i.e., the fork end, can be formed. Students have to use correct symbols and diagrams to explain the formation process.

At a glance, the setting of the question is logical, and it is able to assess students' ability in drawing 3D objects. However, this kind of questions neglects the flexibility of applying software to draw and design. The question hinders and limits students using primitive solid models and Boolean operations, and surely there are other methods to draw the same object without knowing what primitive solid models and Boolean operations exactly are. Students who are able to draw proficiently and apply the CAD skills in real settings may be unable to score higher marks in this question. On the contrary, students who are not proficient in CAD may be able to score higher marks. It is questionable whether the question is assessing computer knowledge or pure geometry. Besides, the question and the model answers suggested do not allow other ways of drawings, and restrict the students' thinking into one absolute answer only.

This example of assessment is not preferable, as it fails to assess (1) students' practical application of using CAD computer software, (2) alternative methods of drawing the objects, and (3) other knowledge associated with CAD. Seemingly, the inflexibility and the limitation of this kind of questions had turned CAD assessment into something unrelated to CAD.

Possible Issues and Difficulties

Although the DSE DAT example above focuses on 3D drawings and the knowledge concerned is not very comprehensive, it provides insights into the discussion of the issues and difficulties in CAD assessment. The following discusses the possible issues and difficulties which are also applicable to a general CAD assessment. It is noted that the discussions are also applicable in computer approach, as paper-and-pencil approach is just a form of assessment and the content in this assessment form should be the same as that in the other form of assessment. The issues and difficulties revealed from paper-and-pencil approach should also be arguable in other approach of CAD assessment.

Too Straightforward and Simple

The contents concerned in most CAD assessment is too focused that the presentation of the question is too straightforward and the answer to the question is too simple. The only task that students have to do is to draw or design from a blank sheet or virtual environment. However, the practical application of CAD is much more than just developing objects or programs. It also includes modifying and optimizing any existing designs. Trouble shootings are inevitable in CAD while design is complicated and detailed. It is possible that these elements are lacking in CAD assessment, and questions are unable to assess students' ability to trouble shoot. In order to expand the scope of the questions and the CAD knowledge assessed, it is necessary to reconsider the question proposition.

Obscure Assessment Content

As illustrated in the example in the previous section, sometimes what is being assessed in CAD assessment is not exactly the CAD knowledge but knowledge related to mathematics or geometry. Although CAD needs to be supported by different knowledge, it is necessary to be reminded that CAD, as its name, is about design. The ultimate goal of CAD is to use computer technology and other knowledge to support design. Subsequently, design elements are crucial in CAD assessment. CAD assessment without design elements may not be trustworthy. However, it is easy to fall into the trap of just assessing technical or operational aspect of CAD and ignoring its original intention.

Lack of Flexibility

CAD assessment lacks flexibility of considering different software. This happens often when 3D drawing software is concerned. For instance, some 3D drawing software is able to merge or joint objects together even when they overlap

with other, while some other software can only merge objects when they are perfectly matched. It is difficult for a CAD assessment to address both software, especially when the software is not specified in the paper-and-pencil approach. Although it is possible to allow the flexibility and request students to suggest which software should be used, marking tasks would be very complicated, and it would be difficult to judge how many scores a student can get if the student cannot finish the drawing.

Too Output-Oriented

The previous discussions voice a concern that CAD assessment is often too output-oriented. In other words, whether a student is able to complete the requested task is more important than the process of thinking and designing. The computer approach suffers from obvious inadequacy in this regard. It often devaluates the design and development process and emphasize the objects or program. The issue in paper-and-pencil approach is less serious, as the steps and the development process may be clearly illustrated on paper in the examination. It is easily to assess the process by using the paper-and-pencil approach.

SOLUTIONS AND RECOMMENDATIONS

In view of the above issues and difficulties of CAD assessment, recommendations are suggested as below. Each recommendation corresponds to an issue in the previous section. It is noted that these are not the only recommendations that CAD assessment can be improved. There are other feasible methods, and the followings are some directions which help developing and designing CAD assessment.

Problem Solving

Problem solving plays an important role in design (Liddament, 1996; Siu, 2002, 2008), and provided

that the ultimate goal of CAD is to design, problem solving elements should be included in CAD assessment. Modifying and optimizing designs or programs can be one of the tasks in the assessment. The assessment should not be limited in producing new designs but also rectifying old ones. This is able to assess students' ability of applying CAD in different situations, and this is also a way to identify students who have advanced skills of CAD. Only those with advanced skills are able to solve complicated or problematic situation in the CAD context.

Design-Oriented

As mentioned earlier, one of the major goals in CAD is to design. Therefore, CAD assessment, and also CAD curriculum, should be design-oriented. In other words, the role of computer technology in assisting design should be clearly demonstrated. The tasks in CAD assessment should be situated in a design scenario that the computer technology is a tool to achieve the desired results. It is surely absurd in some occasions that the assessment focuses on design but not the knowledge of computer operation; however, it is also the only way to prevent CAD education from turning into a pure technical and operational curriculum.

Concept-Oriented

CAD assessment should also consider the possibility of different computer software. CAD assessment should be flexible enough to allow students answering differently based on the functions of different software. For instance, in the example of the DSE DAT examination, rather than Boolean operations, the question should allow students to use other ways to represent the process of 3D drawing. The marking scheme should also allow flexibility in model development. This means the assessment should focus on the general concept of using CAD instead of limiting to specific software or a particular way of designing.

Process-Oriented

In order to less focus on the design output of CAD, in CAD assessment it is suggested that more emphasis can be placed on the process of designing. The process of how the problem is solved or how the students approach a problem should also be considered in CAD assessment. It is important to be process-oriented because the designing process itself is also the CAD learning process, and this can motivate students to do better in the learning process. However, this does not mean that the output is unimportant. The quality of the output is still important in CAD assessment, as it still governs whether the output is applicable. The suggestion here only highlights the necessity of considering the process together with the design output.

FUTURE RESEARCH DIRECTIONS

The recommendations above are yet put into large-scale practice. Therefore, one of the possible future research directions is to implement the CAD assessment which fulfills the recommendations and receive feedback from students and tutors or lecturers. For instance, tutors or lecturers can be asked to design assessment which focuses on designing and problem solving questions, and check or investigate in (1) the feasibility for the tutors or lecturers to design a proper assessment based on the requirement, (2) the time they needed for designing such assessment, (3) students' performance in this assessment, and (4) verbal feedback from students and tutors. It is also possible to compare students' scores in previous assessment with the new assessment to see the differences. The findings should be able to provide insight on how CAD assessment should be improved in the future.

The future research directions of CAD education and assessment should focus on problem solving skills instead of the practical skills. Focusing on soft skill is crucial to develop a more

mature education, and the skills learnt should be transferable so that students cannot only develop their skills but also expand their cognitive abilities (Siu & Chen, 2011; Siu & Wong, 2014). Correspondingly, future research can emphasize the development of cognitive abilities after learning CAD. The cognitive abilities can be assessed through some well-developed tests such as the Cognitive Abilities Test (CogAT). Pre-test or pro-test can be conducted to analyze whether a specific kind of CAD teaching methods or arrangement could develop students' cognitive abilities. Besides, the cognitive performance of a group of students who have learnt CAD and a control group can be compared to explicate the benefits of learning CAD. Although there is no similar empirical research about the relationship between CAD and cognitive ability, PiegI (2005) pinpointed the issues related human cognition and CAD. There is also a number of researches about the relationship between computer and cognition. For instance, several decades ago Clements and Gullo (1984) had already started to study the effects of computer programming on children's cognitive ability.

Another possibility is to investigate the transferability of CAD knowledge. As CAD is supported by knowledge of mathematics, spatial reasoning and solid geometry (Field, 2004), it is possible to correlate students' performance in CAD with the performance in other related field. The results are able to suggest which kind of students the CAD industry needs and provide information how students will perform in CAD in the future. It is exceptionally important while admission or recruitment is concerned, and this helps allocating resources more wisely.

CONCLUSION

The chapter discusses CAD education and the inadequate focus on CAD assessment. It also highlights the issues and difficulties of CAD assessment through reviewing questions related to

CAD in a public examination in Hong Kong. The four issues and difficulties, namely too straightforward and simple, obscure assessment content, lack of flexibility and too output-oriented results in four corresponding recommendations: problem solving, design-oriented, concept-oriented and process oriented. These recommendations are meant to improve the current practices of CAD assessment and encourage CAD tutors and lecturers aiming for a higher standard of CAD education and assessment. These are just some of many possible resolutions and approaches to improve CAD education and its assessment, and there are still many more waiting for discussion and exploration.

Apparently, there is a dilemma in balancing the breadth and depth of the examination content through the typical assessment method. In addition, the typical CAD assessment is unable to assess students with high ability and advanced CAD skills. The issues identified in this chapter are not new, and they have been existing in various CAD examinations – not only those in Hong Kong. Especially in institutes or schools where formal and formative assessments are imperative, the issues are not yet improved. It can be argued that in a certain extent the development of CAD education and its assessment are stagnating. More efforts of investigating the current situation and improving the current practice is crucial for the future development.

ACKNOWLEDGMENT

The authors would like to thank The Hong Kong Polytechnic University for the research support. Wuhan University of Technology provided partial support for the final preparation of the chapter.

KEY TERMS AND DEFINITIONS

CAD Assessment: The strategies or methods in assessing the knowledge or skills acquired in CAD. In this chapter, it refers to assessment at any levels.

CAD Education: The learning and teaching activities of CAD. This is a collective term including all kinds of education in various learning institutes and schools at different levels.

Computer Approach: The approach of using computer to assess CAD ability of students.

Computer-Aided Design (CAD): The design activities which are aided by computer technology.

These design activities include creation, analysis, modification and evaluation.

Design and Applied Technology: A secondary school subject in the Hong Kong Diploma of Secondary Education. It focuses on problem solving through hands-on design activities.

Paper-and-Pencil Approach: The approach of using paper and pencil to assess CAD ability of students.

Problem Solving: The physical and cognitive activity of solving a problem. In this chapter, it refers to one of the essential roles of design and also CAD.

S

The Challenges of Teaching and Learning Software Programming to Novice Students

Seyed Reza Shahamiri

Manukau Institute of Technology, New Zealand

INTRODUCTION

Software Engineering is an engineering discipline that involves with all aspect of software development that applies engineering approaches in order to deliver high quality software products (Pressman, 2005). One of the important stages of software production is coding in which software blueprints are realized via a programming language; a programming language is a language that is understandable for computers (Somerville, 2007). Table 1 shows the general phases of software development. Coding and programming language skills are required from phase four but knowledge and understanding of programming language is very helpful in previous phases in order to successfully complete a software project.

There has been a dramatic demand increase for software applications that promises a rewarding carrier for those who poses the required skills. With the fast advances in technology and emerging ones like driverless cars, Internet of Things (IoT) (Pandya & Champaneria, 2015), Big Data

(Sharma & Mangat, 2015), Software Defined Networks (Bizanis & Kuipers, 2016) etc. it is expected that more software programmers will be required in the future. As the result of such demands, various online and offline courses to introductory programming have been provided.

While knowing software coding is a very useful skill, it is difficult to learn programming especially at the beginning level since acquisition of complex new knowledge, associated strategies, and practical skills are required (Robins, Rountree, & Rountree, 2003). Software development courses are generally among difficult subjects and have low pass rates; according to (Dehnadi & Bornat, 2006) the fail rate of first programming papers in university computer science programmes can be up to 60 percent.

However, what are the reasons that make learning and teaching programming difficult? Why do students find it so challenging? And, why the success rates of programming classes are amongst the lowest in computer science papers? The next section tries to identify the reasons and issues

Table 1. Generic software development life cycle phases

No	Name	Description
1	<i>Planning</i>	The planning phase is the fundamental process of understanding why an information system should be built and determining how the project team will go about building it.
2	<i>Analysis</i>	The analysis phase answers the questions of who will use the system, what the system will do, and where and when it will be used.
3	<i>Design</i>	Based on the user requirements, planning and the detailed analysis, the new system must be designed i.e. a blueprint of the system is created by designing the technical architecture.
4	<i>Implementation</i>	Actually implementing the designed system; writing software programs using software languages.
5	<i>Testing</i>	Checking whether the implemented software works according to specified requirements; fixing bugs/errors.
6	<i>Maintenance</i>	To ensure that the implemented system is properly functioning as per the requirements.

DOI: 10.4018/978-1-5225-2255-3.ch643

that make learning introductory programming challenging. Next, some teaching and learning guidelines are provided to facilitate some of the identified challenges. Finally, recommendations for future studies are provided. The guidelines provided in this chapter are based on the literature and the author's extensive experience in teaching software programming.

BACKGROUND

This section provides a background of the problem and explains the issues in software programming teaching and learning.

Since software is intangible and cannot be seen or touched, creating software products can be a very complex task in comparison to most of the other engineering products; a software project can fail easily and lead to poor quality and unreliable products (Ammann & Offutt, 2008). On the other hand, software applications play very important and critical roles in modern life because they control vital operations that require attributes such as security, reliability, performance, etc., qualities that are hard to achieve (Spillner, Linz, & Schaefer, 2007).

Because of the intangible nature of software, and since students cannot directly sense what they have created, it can become very complex to them to successfully implement, debug and verify the product. In addition, it is more challenging to teach and learn the introduction of coding since this is where the students understand the very basics of software nature and expose to entities and concepts that are generally new to them. They also need to design algorithms and implement them via programming language tools and commands in order to perform the required software functionalities.

Although teaching and learning a programming language may be seen as teaching human languages such as English, it is much more complicated. Teaching a human language is mainly concerned about the language syntax, learning the vocabularies, and how to put them in to use.

This part is similar to teaching programming language as there are syntax and vocabularies (i.e. commands) with specific meanings in that particular language. The main difference is, in teaching human languages we show the students the tools to express their thought and feelings in order to communicate, but we do not teach them what to say. To put it differently, we all know what we want to say, typically, but we may not know how to do it in a particular language. On the other hand, with programming languages we need to teach our students what to ask a computer together with how to ask it, and we need to be very specific while following the language syntax and steps of the algorithms thoroughly as computers have zero tolerance in regards to syntax errors. In other words, computer programs do not run even with a single syntax error.

Furthermore, there is a difference between coding knowledge and strategies. The former provides a declarative nature of programming, such as being able to state how an algorithm works, but the last deals with the practical applications of the knowledge, such as how and where to apply the algorithm (Davies, 1993). Programmers need to think outside the box and be creative in applying and creating knowledge in order to formulate a software solution.

Essentially learning programming requires the learners to develop their problem solving skills. As mentioned earlier, the first step of software development is to understand the problem domain, analyze it, and then to propose a solution including design concepts and algorithms to perform the required functionalities. The next step is to relaying commands to computer systems using a programming language in order to implement the designs and algorithms. The challenge is, regardless of how experience the programmer is, there will be various errors either due to syntax mismatch or incorrect semantic, and they need to deal with unexpected program behaviors frequently. Although modern Integrated Development Environments (IDEs) perform analysis on the code to highlight most of the syntax errors and some obvious compile

time errors, in-depth code inspection and analysis are still required to identify and solve the error in most situations specially run-time errors. To put it differently, learning programming involves different types of cognitive activities and mental representations. They are related to designing programs, understanding them, modifying the code, and debugging them. Construction of conceptual knowledge and structuring of basic and advance programming commands are required even at the lower levels.

During the development the students may need to use a variety of other software applications for graphic and multimedia design, note taking, database development, software design, etc., in addition to the IDE being used. The range of these kind of tools can be from familiar applications like Microsoft Word and PowerPoint to more specialized software like Adobe Photoshop. Teaching students how to use these applications is another issue.

The above challenges are mostly connected causing a shock to novice programmers. The fact that they need to deal with all these difficulties at once may discourage them; they may ultimately give up.

According to (Hubert Lederer Dreyfus, 1986) there are five stages to be an expert programmer namely novice, advanced beginner, competence, proficiency, and finally expert. Winslow (Winslow, 1996) explains a novice programmer as:

- Their abilities to organize knowledge is limited and superficial,
- Their mental model is abstract,
- They are incapable of applying relevant knowledge,
- Their approach to programming is line-by-line instead of understanding the structure.

Experience software engineers already develop the skills to act independently or use other resources, such as programming online communities, to find a fix for the errors they face during software development. Nonetheless, novice programmers

highly depend on an expert to advise them- an experience lecturer who can constantly monitor and observe the students may significantly help them to accomplish the first steps until they are skilled enough to be independent.

SOLUTIONS AND RECOMMENDATIONS

This section tries to answer the question of how to improve the programming classes success rate.

Most students give up early and loose interest when they face the complexities involve in learning software coding; hence, the teaching methodology and the method of delivery is critical. In order to avoid disengaging students, lecturers need to adopt techniques and tools that help students to sense and understand what goes inside the computers and to engage more senses than teaching traditional subjects like Science, Arts, etc. Lecturers need to understand the cognitive requirements of teaching and learning programing and study the successful and unsuccessful strategies.

As an educational program, blended delivery deals with the use of digital and online media in teaching and learning that not only helps learners to involve more senses during the learning process but also give them tools to help them with their studies (Sankey, Birch, & Gardiner, 2010). Furthermore, blended delivery gives more freedom to students in having some control over where and when to learn. It is shown that blended delivery models may ease the learning procedure when face-to-face delivery is combined with computer-mediated activities. In addition, multimodal learning can specifically be helpful for lower-achieving students (Rabiner & Sambur, 1975).

Approaches to teach software programming in which blended delivery combined with activity based learning can be very helpful to maximize the effectiveness of teaching programming. Such approaches help students to visualize the software solutions and understand them better. They may also help to make software somehow tangible. The

Figure 1. Microsoft Visual Studio 2015 IDE

delivery medium is also very important. There are a variety of techniques that can, and must be, considered so that students benefit most from the classes. For example, combining PowerPoints and slides (or other ways of visualizations) with lecturer explanations can be effective to show the main parts of the algorithm being implemented and to provide visualizations of how the algorithm works. Using different colors to highlight key points in the slides and different graphics to explain processes and summarizing content are helpful because they can help students to both hear and see the content and capture information and key points so that more senses are engaged. They can also be used as a reference when students perform self-study, and when face to face lecture is not possible.

Traditionally lecturers use a mixture of techniques that include the lecturer explaining the concepts, and then provide exercises in order to emphasis on learning by doing. Blended delivery can be well integrated with this method of teaching.

Students should be encouraged to use an IDE to formulate a software solution. IDE itself is a software solution that provides a platform for development by providing tools to help the programmers plan, organize, implement, verify,

and refactor coding projects. Some IDEs are very user friendly and convenient as they provide all the tools required for software development and documentations of how to use them. Nonetheless, there are only few IDEs for some of the programming languages, such as C#.Net, that provide all the required tools; hence, there are limitations in regards to the programming language being though. Current examples of well-known IDEs are Microsoft Visual Studio, Android Studio, NetBeans, and Eclipse.

Figure 1 shows a snapshot of Microsoft Visual Studio that is the primary IDE to develop software applications for Windows based platforms and figure 2 is a snapshot of Android Studio to develop applications for Android platforms. Teaching how to effectively employ tools provided by an IDE must be a part of teaching any programming paper, which can be complicated as they are complex software solutions themselves.

It is important that software programmers be independent and capable of taking initiative. Lecturers need to coach students and help them to search for solutions for their programming problems. Skills to find answers from various sources like textbooks, online communities, online video providers, etc. are crucial.

Figure 2. Android Studio IDE

Programming for different platforms and different types of software, like embedded software, data analytics software, mobile platforms, web services, etc. requires additional understandings of the platforms in addition to knowing the programming and problem solving basics. These basics of programming are generally the same regardless of the software purpose and platform specifically for introduction to programming courses. Once students understand the fundamentals of programming and the way to instruct computers and formulate the instructions, higher level programming courses may concentrate more on programming for specific platforms.

Recently there are new methods of teaching programming widely being used on the Internet in which one-way communication techniques are used to teach software programming. One of the most popular methods is using video lectures that capture the lecturer teaching coding while showing and explaining the code. Students are expected to watch the videos and follow the instructions to learn the subject; lessons are usually followed by related exercises and projects. There are hundreds of hours of video on teaching different program-

ming topics for various programming languages and platforms on YouTube. Some online education providers, like Udacity.com and Lynda.com, employ such techniques as the main method of delivering the lessons. Using such methods are helpful as supplementary materials in conjunction to face-to-face delivery.

FUTURE RESEARCH DIRECTIONS

The best approach to learn programming for novice students is practice. Future works need to study approaches in which lecturers provide many programming exercises for students and monitor the students' performance by completing the exercises in order to identify the gaps in their programming skills. They can then put more emphasis on the identified gaps by designing specific lessons and exercises. Providing resources to point to additional exercises is also helpful.

An important skill that every programmer must well develop is "learn how to learn". Programmers often face coding challenges that are new to them. This is where their research and problem

solving skills play a key role as they need to use available resources to extract information and train themselves to learn the necessary skills in order to solve the coding challenge. Hence, lecturers must consider exercises to develop such skills.

In addition, techniques like pair programming can be effective in which two students work on a tasks together while explaining and debating their understanding of the task, and helping each other to design algorithms and implement them.

CONCLUSION

As software applications play a vital role in our daily life, there is a need to have more skilled programmers to create such software products. There are various emerging disciplines like Internet of Things, driverless cars, Data Science, Software Defined Networks, etc. that demand more programmers in the near future hence a more promising carrier for software developers is expected. Nevertheless, we have seen a low success rate in programming classes where some students lose interest to learn the required skills as they find programming a software a very challenging task; it has been reported that the fail rate of first programming papers in university computer science programmes can be up to 60 percent. This chapter looked at some of the issues in regards to teaching and learning software programming and the nature of programming that may negatively influence the students' attention. Remedies to tackle the issues were also provided emphasizing on blended delivery using the technologies to facilitate the learning, and techniques that encourage more practice by coding exercises. Special attention on developing "learn how to learn" skills is also discussed.

KEY TERMS AND DEFINITIONS

Blended Delivery: Deals with the use of digital and online media in teaching and learning that helps learners to involve more senses during the learning process and also give them tools to help them with their studies.

Integrated Development Environment: A software solution that provides a platform for software development by providing tools to help the programmers plan, organize, implement, verify, and refactor coding projects.

Introductory to Programming: The initial phase of teaching and learning software programming in which the concentration is on coding basics, problem solving basics, programming language syntax, and primary computer language tools and concept such as variables, loops, decision making, logical and arithmetic operators, etc.

Programming Language: A language that is understandable for computers.

Software: A part of a computer-based system that provides instructions for hardware.

Software Development Life Cycle: Generic steps of constructing software products and the life cycle of a typical software.

Software Engineering: An engineering discipline that involves with all aspect of software development that applies engineering approaches in order to deliver high quality software products.

Developing a Glossary for Software Projects

S

Tamer Abdou*Suez Canal University, Egypt***Pankaj Kamthan***Concordia University, Canada***Nazlie Shahmir***WestJet Airlines Limited, Canada*

INTRODUCTION

There is increasingly significant role played by software in society. This has led to attention on the practices of developing and maintaining software that aim to be successful for all the stakeholders involved.

The discipline of software engineering advocates a systematic and disciplined approach towards the development and evolution of software systems. There is a domain underlying every software project. For a software project to be successful, it is imperative that the domain knowledge be understood and communicated properly to all the stakeholders of that project (Schneider, 2009). Indeed, lack of adequate understanding of the domain has been cited as one of the reasons for software project failures (Kliem, 2007).

The purpose of this chapter is to draw attention to one of the initial steps towards building shareable domain knowledge for a software project, namely a glossary. In doing so, it aims to be relevant to professional as well as pedagogical settings.

The rest of the chapter is organized as follows. First, a motivation and background on glossary are presented, and discussion of relevant previous work is outlined. This is followed by details of a process for developing a glossary. Next, directions for future research are highlighted. Finally, concluding remarks are given.

BACKGROUND

In this chapter, the terms ‘software project’ and ‘project’ are considered synonymous, unless otherwise stated. The term ‘project’ is used to emphasize the fact that the notion of glossary is applicable to a variety of projects, including, but not limited to, software projects. A software project may be about development or about maintenance of a software product.

The following definitions are essential for the rest of the chapter. A *domain* is an area of interest (or the universe of discourse). A *glossary* is a list of terms in a particular domain of knowledge with the definitions for those terms. A *stakeholder* is an individual, group, and/or organization, having an interest in a project.

Glossary in Context

The history of use of glossary in software projects goes back to mid-to-late-1960s, and is therefore is almost as old as the discipline of software engineering itself.

A glossary is similar to, but different from, a dictionary, lexicon, and thesaurus. A comparison can be made using the criteria of goal and scope.

Goal

A glossary, like a dictionary, presents its terms (and corresponding definitions) in a lexicographical (alphabetical) order. Also, a glossary, like a thesaurus, may include synonyms of its terms, but does not include antonyms of any terms. For example, in a *Glossary of Requirements Engineering Terminology* (Glinz, 2014), bug, defect, and fault are considered synonymous. However, unlike a lexicon, a glossary usually does not point to etymology of a term.

Scope

A glossary is specific to the scope of a project, while dictionary, lexicon, and thesaurus are more general in scope as implied by the type of information they include.

Motivation for a Glossary

There are a number of (not necessarily mutually exclusive) reasons for having a glossary for any project.

Support for Knowledge Engineering

It has been acknowledged for some time that software engineering is a knowledge-intensive discipline (Robillard, 1999). For example, there is acquisition of knowledge during all stages of software development. The development of a glossary is an initial step towards knowledge engineering (Schneider, 2009).

The purpose of a glossary is to help make implicit domain expert knowledge *explicit* (Dalkir, 2011), help avoid incurring *analysis debt* due to inconsistent terminology, and to ensure that the knowledge of the domain underlying a software project be communicated properly to all the stakeholders of that project.

Communication Among Stakeholders

It has been pointed out in a number of contexts that the quality of communication among stakeholders is crucial for the success of a project (Kliem, 2007). There are several dimensions of the quality of communication, one of which is common understanding of the domain underlying the project. It is therefore crucial to create a placeholder of commonly-agreed upon domain knowledge (Kovitz, 1999).

A project-related discourse, whether expressed verbally or in writing, consists of sentences in some language (usually, natural language). A sentence can include terms that may or may not be understood universally. A glossary makes a discourse meaningful by ensuring that all the stakeholders involved in the discourse are on the “same page”. A glossary is a placeholder for commonly-agreed terms (Gottesdiener, 2005).

Figure 1 illustrates the pairwise relationships that can arise between stakeholders and a project artifact, between stakeholders, and the role of a glossary in enabling these relationships.

The need for a glossary is especially acute in organizations where, historically, there has been compartmentalization of departments with more conflict than cooperation between them, but effort is being made to change the trend. For example, *DevOps* is a recent initiative towards a better alignment and working relationship between *development* and *operations* (Hüttermann, 2012). To accomplish that, DevOps extends lessons learned from agile software development and aims to foster close collaboration, culture of shared goals and values, and commitment to measurement and monitoring (Lwakatare, Kuvaja, & Oivo, 2015). For these to manifest successfully, the presence of a common language of communication is a necessary requisite, which a glossary can help provide.

Figure 1. A glossary helps communicate the intent of an author of a project artifact to the reader of that artifact

Reduction of Semantic Heterogeneity in Natural Language

In coming across a term, a stakeholder either (1) is aware of the meaning of the term in one context, but not necessarily other contexts, or (2) is unaware of the meaning of the term. For example, (1) can occur for old terms (that is, terms in existence) and (2) can occur for new terms.

There are certain linguistic structures, for instance, homonyms, metonyms, neologisms, polysemes, portmanteaus, and synonyms, in natural languages such as English. These structures enrich a language, but are also create semantic heterogeneity, which can lead to misunderstandings by stakeholders in different ways.

For example, the meanings of the term ‘task’ in *Interaction Design* and in *Scrum*, an agile software development methodology, are different. It has been the experience of one of the authors that even those who are working in industry and specializing in an area (such as, quality assurance) use certain terms with closely-related meanings (such as, ‘smoke test’ and ‘sanity test’) synonymously. The meanings of the same term across different standards can also vary. It is difficult to make meaningful comparisons between entities if the meanings of the two entities are different.

In many agile software development methodologies (Highsmith, 2009), software requirements are expressed as user stories. Figure 2 shows that a reserved term in a user story could point to the project glossary to avoid potential ambiguity and/or to provide clarity to a reader.

Inherent Human Limitations

The software engineers working on the same project may come from different educational backgrounds. These engineers may also be unaware of variations in each other’s backgrounds. This is especially the case for members of teams that are geographically distributed.

Figure 2. A reserved term in a user story card points to the glossary for disambiguation and/or clarification

It is not uncommon for software engineers to work on multiple projects at the same time. In some cases, software engineers are hired on a contract in the middle of a project, and need to familiarize themselves with the domain knowledge. If a software system is aimed for maintenance, then the maintenance team may not be identical to the development team, and may need to consult appropriate documentation for certain activities, such as reengineering, deemed necessary.

For many projects, especially large-scale projects with non-trivial domains, it is unrealistic to expect from every project stakeholder to know, or be able to (correctly) recall, the purpose and meaning of all necessary domain-specific terms, all the time.

In such cases, a glossary can be used as a reference.

Stakeholders of a Glossary

There are a variety of stakeholders for a given project. A glossary, as a *boundary object*, may be used by any stakeholder of a project, and for different reasons.

For example, a project manager may rely on a glossary to support an executive summary; a requirements engineer may use a glossary for domain-specific terms in requirements or otherwise; a designer may use a glossary for defining terms from object-oriented design, user interface design, or other terms in the solution domain; a programmer may use a glossary before deciding upon the style of constant and variable names in a program; a tester may use a glossary to get clarity on a known concept before writing test cases; a non-technical stakeholder (say, a representative user in participatory design) may use a glossary to understand a concept before a meeting; and so on.

Related Work

For the past couple of decades, there have been concerns raised about a lack of a consistent terminology in software engineering (Fenton &

Pfleeger, 1997). This issue, unfortunately, has not been resolved years later, and there are no apparent signs that it will be resolved any time soon.

For example, it has been pointed out (Grimstad, Jørgensen, & Moløkken-Østvold, 2006) that the term ‘effort estimate’ has not been properly used in a number of textbooks and research articles, and it has been pointed out in (Maedche, Botzenhardt, & Neer, 2012) that “a major potential terminological pitfall needs to be addressed [...] user experience (UX) design, user interface (UI) design, graphical user interface (GUI) design, user-centered design (UCD), interaction design (IxD) and additional terms and acronyms are used interchangeably [...] leading to additional confusion”.

The significance of glossary has been acknowledged broadly and explicitly in different contexts in software engineering literature. The significant role that a glossary can play in a software project has been highlighted in form of the *Tip 54 Use a Project Glossary* (Hunt & Thomas, 2000). *Develop a Glossary to Define a Common Language* is one of the recommended best practices in use case modeling (Gottesdiener, 2003). *Define Your Terms* has been proposed as one of the basic principles of writing (Miller, 2004). Finally, *Define a Glossary* is one of the recommended software engineering quality practices (Kandt, 2006). There is native support for glossary in the *Rational Unified Process* (RUP) and the *Open Unified Process* (OpenUP).

The need for a glossary is especially acute in software requirements engineering (Leffingwell, 2011; Wiegers & Beatty, 2013) as it is among the earliest stages in a process where the stakeholders converge. The role of a glossary in reducing lexical ambiguity in software requirements has been emphasized (Kamsties, Berry, & Krieger, 2003). It has been said that “[a requirements engineer] should not make assumptions about the experience or expertise of the reader”, and in stating so, development of a glossary is recommended (Sommerville, 2011). Glossary is part of the *Software Product Certification Model* (SPCM) (Heck, Klabbers, & Eekelen, 2010) and of the *JIT*

Requirements Quality Framework (Heck & Zaidman, 2015). The use of a glossary in contributing towards the traceability of software requirements has been highlighted (Cleland-Huang, Gotel, & Zisman, 2012). In particular, a glossary can serve as a resource for terms in a trace source artifact or in a trace target artifact.

An Exploration of Glossary Engineering

The significance of a glossary for a project calls for a comprehensive approach towards its development.

Requisites for Developing a Glossary

There are certain necessary requisites for developing a glossary properly.

Capabilities of an Author of a Glossary

There can be one or more authors of a glossary. The development of a glossary for a software project requires proper understanding of at least the problem and solutions domains corresponding to the project in question. This, however, can be Catch-22.

It also requires ability in technical writing, as, for example, outlined in the *Software Engineering Professional Practice* (SEPP) Knowledge Area (KA) of the *Guide to the Software Engineering Body of Knowledge* (SWEBOK) or the *Software Engineering Competency Model* (SWECOM). This includes at least a rudimentary background in linguistics.

Experiential Knowledge for Developing a Glossary

The presence of experiential knowledge, that is, knowledge acquired and agreed upon by a collective over time, can be useful for developing a glossary. Indeed, there are guidelines for developing

a glossary (Kovitz, 1999), and there is a pattern named GLOSSARY (Rüping, 2003).

A Process for Developing a Glossary

To be systematic, a process for developing a glossary is proposed and termed GDP for reference. GDP has a number of characteristics:

- **Applicability:** It is independent of any particular application domain, software methodology, or information technology, and is therefore broadly applicable.
- **Correctability:** It is iterative (as suggested by the nonlinearity in the sequence of steps).
- **Feasibility:** It is manual (although it could be partially automated if suitable tools, such as those with support for natural language processing, are available).

The steps underlying GDP and the interrelationships among the steps are shown in Figure 3, and are described in detail subsequently.

Step 1: Planning

The personnel involved, schedule, and the use of experiential knowledge need to be decided. The candidate personnel may include those who are external to a software project team, as well as those who are internal to a software project team. For example, candidate personnel can be domain experts (also known as subject matter experts) as well as requirements engineers.

The potential for reuse should also be assessed. There could be a number of candidate sources for reuse. For example, there may already exist glossaries in the organization, from past, similar projects, or otherwise. For the *same* software product, the glossary for its development project is a prime candidate for its maintenance project. These other sources could be statement of project vision and documentation on organizational business processes.

Figure 3. A glossary development process

Step 2: Eliciting Terms

The term could be elicited using a number of complementary approaches, including ethnography (interviews or surveys), brainstorming and mind mapping, and past, similar projects.

The terms in the glossary may include those that do not have a universally common interpretation, and those that are newly introduced or at least uncommon. These terms could take the form of abbreviations (including acronyms and initialisms), numeronyms, single word, or a combination of multiple words (phrases).

There needs to be a consensus across the members of a project team on the terms to be included in a glossary. To do that, glossary development should be a collaborative effort.

Step 3: Formulating Definitions

There are different kinds of definitions, of which lexical definitions, operational definitions, and stipulative definitions, are most suited for a glossary. The definition of a term should not be circular.

(For example, this can happen if the definition is tautologous to the term.) The definition should, as far as possible, be self-contained. If possible, multiple definitions of a single term should be avoided. If not, then the context to which each definition applies must be mentioned.

The definitions could be (1) original, (2) variations (adaptations) of existing definitions, or (3) replications of existing definitions. In cases of (2) and (3), there must be a suitable citation.

There needs to be, once again, a consensus across the members of a project team on the definitions to be included in a glossary.

Step 4: Representing and Presenting

The terms and their definitions can be represented (for machine consumption) and presented (for human consumption), in different formats, in different modalities, targeted for different mediums. The order of terms in a glossary is usually lexicographical (alphabetical). The issue of representation and presentation is discussed in more detail later.

Step 5: Reviewing

The necessity and sufficiency of terms, and the definitions of the terms, needs to be inspected, preferably by others not involved in the development of the glossary. This can lead to revisiting one or more previous steps.

Step 6: Publishing

There are a number of means for publishing a glossary. A glossary must be published in a manner that it is available to all relevant stakeholders. Indeed, *Display Models Publicly* is one of the practices of *Agile Modeling* (Ambler, 2002) applicable to the context of a glossary.

Managing the Process for Developing a Glossary

It could be noted that a single-pass, upfront development of a complete glossary can be difficult, as, at inception, required knowledge may not be known, the required expertise may not be present, or new terms may appear during the execution of the project.

Therefore, once an initial version of glossary is developed, it should evolve iteratively and incrementally throughout the project, based on the needs of that project. This means that GDP should start before a software development process, and, subsequently, run in parallel.

In general, a glossary is a ‘living’ document that evolves throughout the life of a project. Therefore, each evolution (increment/iteration) of the glossary should be associated with unique version information.

Indeed, past versions can be useful, especially if they provide information on a term that is deleted in a later version, if they provide information on a certain reference that is removed in a later version, and so on.

Challenges in Developing a Glossary

S

There are a number of challenges to GDP, including the following:

- **Recursion.** The definition of one term may include one or more other terms. For example, it can be expected that the definition of *risk management* will include a number of terms, including *risk*. These other terms themselves may need to be defined. Furthermore, to avoid terminological explosion, there needs to be a stopping criteria.
- **Inconsistency.** The definition of one term should not contradict the definition of another term, at least within the same glossary. It is also important that the definition of a term does not vary drastically across glossaries for different projects, at least across those starting and ending in the same time period. A consistent use of terms is contingent upon long-term stability of those terms. The definition of a term can change over time if new knowledge about the term is discovered.
- **Similarity.** The definitions of two (or more) terms should not be similar to the point that their meanings are difficult to distinguish. For example, the difference between *acceptance test* and *user acceptance test* may not be obvious, unless there is an explicit effort to do so.

Representing a Glossary

There are certain established approaches for representing a glossary, although currently there is no ‘standard’. These approaches rely on the *Extensible Markup Language* (XML).

Figure 4. A partial glossary instance in DocBook 5

```
<glossary>
<title>[Name of Project] Glossary</title>
<!-- ... -->
<glossdiv>
  <title>P</title>
  <glossentry xml:id="pml">
    <glossterm>Pattern Markup Language</glossterm>
    <acronym>PML</acronym>
    <glossdef>
      <para>...</para>
      <glossseealso otherterm="xml"/>
    </glossdef>
  </glossentry>
</glossdiv>
<!-- ... -->
</glossary>
```

Approach 1: DocBook

It is possible to use DocBook (Walsh & Hamilton, 2010). Figure 4 shows a conforming document, in DocBook 5, for a glossary.

The glossseealso element provides relationships among terms in the glossary.

Approach 2: GlossML

It is possible to use the Glossary Markup Language (GlossML). Figure 5 shows a conforming document, in GlossML, for a glossary.

It can be seen in Figure 5 that, by the use of certain attributes, GlossML supports localization and attribution of any resources that are used in the definition of a term.

Presenting a Glossary on the Web

A glossary representation based on one of the aforementioned approaches can be transformed to one or more suitable glossary presentations, as shown in Figure 6.

The set of candidate choices for glossary presentations can vary over time (for example, can be

</glossary>
```

Figure 6. From a single glossary representation to multiple glossary presentations

influenced by the needs of the stakeholders and the devices deemed relevant for a particular time).

FUTURE RESEARCH DIRECTIONS

There are a few directions for future research that emanate from the work presented in this chapter.

The use of not necessarily textual or not entirely textual modalities for communication in software engineering may necessitate revisitation of the notion of glossary. For example, the use of *semiotic signs*, such as icons or symbols, in requirements engineering to support non-technical stakeholders (Marcus, 2003; Khanom, Heimbürger, & Kärkäinen, 2015) motivates extending the notion of glossary, and modifying the means for representing and presenting it.

The (a) emphasis on, and the use of, a glossary can depend on the (b) culture of an organization involved in software development, in general, and the nature of software development, in particular (Wiegiers, 1996; Hofstede, Hofstede, & Minkov, 2010). For example, communities involved in industrial software development and communities in open source software (OSS) development differ from each other in their style of acquiring

domain knowledge. The (c) impact of incorrect and/or inconsistent domain knowledge on the (d) outcome of a software project can vary considerably. Thus, investigating relationships, such as between (a) and (b), or between (c) and (d), empirically, using a *design science* approach (Johannesson & Perjons, 2014; Wieringa, 2014), for the sake of seeking useful correlations, is of research interest.

The ecosystem of the Social Web includes a variety of applications, including *Wiki*, that enable distributed software engineering. A Wiki has a number of characteristics (Leuf & Cunningham, 2001) that make it a candidate suitable for developing a glossary (and aiding Step 6 of GDP): it is cost-effective, which is especially a consideration for organizations with small budgets; it is possible for people to participate and contribute to the development of a glossary without any particular space or time constraints; there is support for versioning, including reverting back to a previous version if necessary; there is provision for feedback; there are facilities for rich typesetting (such as formatting and hyperlinking); and it is possible for people to access and read the glossary as it develops without any particular constraints on space or time. Therefore, exploring the use of

Wiki for a glossary, in both academia as well as industry, in the realm of agile software projects and otherwise, is another area of research interest.

CONCLUSION

This chapter accentuates the potential uses of a glossary, and contextualizes the challenges in developing a glossary. It presents a systematic approach for developing a glossary, and provides the necessary guidance for doing so.

A glossary does not have any intrinsic value, that is, the value of a glossary does not lie in itself, but that for others (people or products). This has foundational implications towards software engineering education as well as towards software engineering profession. For example, it is crucial that students learning a concept for the first time, or professionals using a concept for the first time, have a clear understanding of that concept and its relation to other concepts in a given context. Indeed, GDP, the glossary development process described in this chapter has implications for *primary learning* (the students learn the significance of a glossary, and learn how to develop and use one properly) as well as *secondary learning* (the students learn how to interact with domain experts, learn how to work collaboratively, and learn how to negotiate and reach consensus in a timely manner), both of which are crucial towards their path of becoming a professional software engineer.

The success of a software project depends intrinsically on effective communication among stakeholders. It has been the experience of the authors that a lack of a proper common ground for terminology continues to be an obstacle towards a transparent communication among software engineers in professional settings, such as those working in industry. There are a number of avenues for creating an environment for an effective communication among stakeholders, and a glossary is one such avenue. A glossary contributes to individual as well as communal understanding of a domain, both of which are necessary for creat-

ing an environment of effective communication among stakeholders.

In conclusion, a glossary is integral to every software project, and therefore developing a glossary is worthwhile.

KEY TERMS AND DEFINITIONS

Agile Software Development Methodology:

A software development methodology based on the Agile Manifesto.

Artifact: A document or a model produced during software development.

Process: A set of interrelated or interacting activities that transforms inputs into outputs for some purpose.

Requirement: A statement which translates or expresses a need and its associated constraints and conditions.

Social Web: The perceived evolution of the Web in a direction that is driven by ‘collective intelligence,’ realized by information technology, and characterized by user participation, openness, and network effects.

Software Engineering: The application of a systematic, disciplined, quantifiable approach to the development, operation, and maintenance of software; that is, the application of engineering to software.

User Story: A high-level requirement statement that contains minimally sufficient information to produce a reasonable estimate of the effort to implement it.

Wiki: A Web application developed cooperatively by a community of users, allowing any user to add, delete, or modify information.

Displaying Hidden Information in Glossaries

INTRODUCTION

All models created during the software development process and specifically during the Requirements Engineering Process, are created with structures and purposes clearly defined. These structures have been conceived to maximize the expressiveness of the model for its objective.

Despite this, and very possibly because of this, it may occur that this models hold information no perceptible during its routine use. From an epistemological point of view, this situation is very similar to what happens in data mining (Artz, 2009). For particular case of Requirements Engineering models, which are written in natural language, it has been observed that at least part of this hidden information can be discovered.

In this chapter, a strategy to visualize the grouping of terms in a glossary called Language Extended Lexicon (LEL) is proposed. Experiments performed on real world cases have shown that the clusters obtained using syntactic resources of the LEL model, coincide with semantic nuclei of the application domain. The proposed strategy is based on graphs constructed using hypertext links embedded in the LEL model.

Disciplines dedicated to the comprehension of phenomena whose dominant aspect is the structural complexity instead of the essential complexity of their components have been acquiring more importance (Barabasi, 2002; Dorogovtsev

& Mendes, 2003). There are many examples, in several disciplines, where the detection of groupings provides a notorious contribution to the comprehension of the phenomenon being studied (Sarmah, Kalita, & Bhattacharyya, 2011; Mo, Cao, & Wang, 2012; Zimmermann, Ntoutsis, Siddiqui, Spiliopoulou, & Kriegel, 2012). Most evident examples of this sort of problems are the organizational networks, social networks, bibliographic references networks and interest groups among many others. The classic visual representation of these networks is done by means of graphs. Actually, it happens that when the number of nodes surpasses a moderated limit, those graphs become not useful to observe the relevant characteristics of the network. Configurations of nodes and connections also occur in a great diversity of other applications. They may represent physical networks, such as electrical circuits, roadways, or organic molecules. They are also used when representing less tangible interactions as might occur in ecosystems, sociological relationships, databases, or in the flow of control in a computer program (Gross & Yellen, 2003, 2006; Kamada & Kawai, 1989).

The requirements prioritization method proposed by Duan, Laurent, Cleland-Huang, & Kwiatkowski (2009), analyzes documents of the Requirements Engineering process by means of detecting clusters of requirements. In Duan proposal, the requirements are included in clusters by

means of an iterative algorithm. Those clusters are object of negotiations among the stakeholders to assign priorities. Requirements inherit the priority assigned to the cluster to which they belong.

Some of the models of the Requirements Engineering may be studied from the structural point of view. Particularly, one of the most promising is the LEL (Leite & Franco, 1990). This model records the vocabulary used in the application domain. It describes the words and phrases used by clients and users with a meaning specific to the application domain.

Observing the LEL from a structural point of view, it may be immediately seen that it can be depicted using a graph where the vertices symbolize the LEL entries and the edges represent the hypertext links among entries.

From this point of view, the LEL may be visualized as a sort of linguistic network with a complex structure; in such a way that besides the explicit information stored in each symbol, there is implicit information stored in the relationships among symbols. To build and to analyze the graph of the symbols of the LEL is a sort of knowledge mining.

The most basic knowledge acquirable from the LEL graph is the existence of clusters of entries, which become roots for any taxonomy of the business process. Intuitively it may be said that if the application domain is divided into areas of interest or organization fragments, then it may be expected some coupling among the terms used in such area.

This chapter describes a mechanism to build the graph of any LEL, offering a good visualization of the existing symbol clusters.

The following section analyses the Language Extended Lexicon (LEL), a glossary built during Requirements Engineering process. Then, a section describing force directed algorithms applied to graph visualization is included. After that, the use of these methods in LEL graph construction is studied. And finally, some results, future work and conclusions are presented.

BACKGROUND

LEL: Language Extended Lexicon

The creation of a glossary defining the jargon used in the application domain has been highlighted since many years ago (Arango, 1994; Leite & Franco, 1990). Moreover, several experiences along decades have shown that these glossaries are, by themselves, an important source of information to acquire knowledge about the application domain. (Ben Achour, Rolland, Maiden, & Souveyet, 1999; Oberg, Probasco, & Ericsson, 1998; Prakash, Aurum, & Kox, 2004; Regnell, 1999; Rolland & Ben Achour, 1998). This fact is very well known by linguistics, since they have established that language reflects environment and technology. Just a few examples of that are i) Arabic which has 80 words for camel, ii) Japanese having more than 20 words for rice and iii) Inuit with more than 20 words for snow and ice. It is not needed to explain the importance of camel, rice, snow and ice for those peoples. (Nettle & Romaine, 2000).

The successful use of glossaries by actual practitioners has been reported for more than two decades (Weidenhaupt, Pohl, Jarke, & Haumer, 1998). The authors of this article have a library of more than 200 real cases glossaries developed by undergraduate students, graduate students, practitioners and themselves. The oldest cases were developed as early as 1990 (Leite & Franco, 1990; Rivero, Doorn, del Fresno, Mauco, Ridao, M., & Leonardi, 1998). Some of the most relevant are:

- A reflexive application of the requirement engineering process to the requirement engineering process itself (García & Gentile, 1999).
- Acquisition, administration and maintenance of ATM equipments, 2003.
- Quality Control of Medicaments Supplies, 2007.

- Integrated Administration System of a Private University, 2010.
- A new version of García and Gentile (1999) actually under development.

The Language Extended Lexicon is a meta-model designed to help the elicitation and representation of the language used in the application context (Leite & Franco 1993; Leite, Doorn, Kaplan, Hadad, & Ridao, 2004; Leite et al., 1997). LEL is a glossary proposed by Leite (1997). This model is centered on the idea that a closed description of language terms improves the comprehension of the Universe of Discourse. It is a natural language representation that aims to capture the vocabulary of an application.

The Lexicon main goal is to register symbols (words or phrases) which are peculiar to the application domain. Each entry in the lexicon is identified by a name or names (case of synonyms) and has two types of descriptions, as opposed to the usual dictionary, which provides only one.

The first, called Notion, is the usual one and its goal is to describe the denotation (defines “what the symbol is”) of the word or the phrase. The second, called Behavioral Response, is intended to describe the connotation (describes “how the symbol acts in the system”) of the word or the phrase, providing extra information about the context at hand. Entries are classified in four types according to its general use in the UoD. The types are: Subject, Object, Verb and State. Figure 1 presents the Language Extended Lexicon Model.

While describing the symbols, two principles have to be followed: the *principle of circularity* that intends to maximize the use of symbols in the description of other symbols and the *principle of minimal vocabulary* that intends to minimize the use of symbols that are external to the lexicon. These external symbols must belong to a small subset of a natural language dictionary. These rules stress the description of the vocabulary as a self-contained and highly connected hypertext (Leite & Franco, 1993).

Figure 1. The Language Extended Lexicon Model

```

LEL: representation of the symbols in the application domain language.
Syntax:
    {Symbol}1N

Symbol: entry of the lexicon that has a special meaning in the application domain.
Syntax:
    {Name}1N + {Notion}1N + {Behavioral Response}1N

Name: identification of the symbol. More than one represents synonyms.
Syntax:
    Word | Phrase

Notion: denotation of the symbol. It must be expressed using references to other symbols and using a minimal vocabulary.
Syntax:
    Sentence

Behavioral Response: connotation of the symbol. It must be expressed using references to other symbols and using a minimal vocabulary.
Syntax:
    Sentence

where Sentence is composed only by Symbols and Non-Symbols, the latter belonging to the minimal vocabulary.
+ means composition, {x} means zero or more occurrences of x, () is used for grouping, | stands for or and [x] denotes that x is optional.

```

Automatic Graph Construction

A graph $G = (V, E)$ is a set V of vertices and a set E of edges, in which an edge joins a pair of vertices. Normally, graphs are depicted with their vertices as points in a plane and their edges as line or curve segments connecting those points. There are different styles of representation, suited to different types of graphs or different purposes of presentation. When drawing graphs, some generally accepted aesthetic criteria are used (Fruchterman & Reingold, 1991):

- Distribute the vertices evenly in the frame.
- Minimize edge crossings.
- Make edge lengths uniform.
- Reflect inherent symmetry.
- Conform to the frame.

However, these types of criteria do not contribute to the objective of visualizing the underlying structure of the analyzed problem.

Notoriously effective graphs may be obtained using automatic Drawing Graph methods. Drawing Graphs is an area of mathematics and computer science that combines methods from geometric graph theory and information visualization to derive two-dimensional depictions (Di Battista, Eades, Tamassia, & Tollis, 1999; Kaufmann & Wagner, 2001).

There are many techniques to draw graph. Most of them are devoted to a specific type of graph such as trees, directed graphs and others. A family of techniques to visualize unspecific graphs is known as *force-directed*. Also known as *spring embedders* (see Figure 2), such algorithms calculate the layout of a graph using only information contained within the structure of the graph itself, rather than

relying on domain-specific knowledge. Graphs drawn with these algorithms tend to be aesthetically pleasing, exhibit symmetries, and usually produce crossing-free layouts for planar graphs (Kobourov, 2013). These methods are flexible, easy to implement and provide excellent results (Walshaw, 2003). This sort of methods is based on physics analogies. Their main characteristics are:

- They model the graph as a mechanical system.
- The graph is obtained equilibrating the mechanical system.

These characteristics define the two main components of the force-directed methods:

- A mechanical model of the graph representing the elements of the graph (vertices and edges), perhaps adding some aesthetic restriction.
- An algorithm to find the equilibrium state of the mechanical system.

Nodes are placed in an arbitrary initial disposition, and the forces move them to its final equilibrium position. The spring layout method of Eades (1984) and the algorithm of Fruchterman and Reingold (1991) both rely on spring forces, similar to those in mechanical laws. In these methods, there are repulsive forces between all nodes, but also attractive forces between nodes which are adjacent. Actually, these repulsive forces come from atomic models where nucleons have strong repulsive forces which prevent the collapse of the nucleus. In the Fruchterman y Reingold algorithm, only adjacent nodes attract themselves, while all nodes have repulsive forces.

Figure 2. Spring Embedder (Adapted from Eades, 1984)

LEL GRAPH CONSTRUCTION USING DIRECTED FORCES

The Fruchterman and Reingold (1991) algorithm was applied to graphs where nodes represent LEL symbols and edges represent the hypertext links among them. Minor changes to the algorithm were done; specifically the forces involved were modified.

The Forces

Used forces are:

$$fa(d) = c1 * \log\left(\frac{d}{c2}\right) \quad (1)$$

$$fr(d) = c3 * \sqrt{d} \quad (2)$$

Figure 3. Force-directed algorithm (Adapted from Fruchterman & Reingold, 1991)

```

area := W * L; { W and L are the width and length of the frame }
G := (V, E); { the vertices are assigned random initial positions }
function fa(delta) := begin return (c1 * log(delta/c2)) end ;
function fr(delta) := begin return (c3 * sqrt(delta)) end ;
for i := 1 to iterations do begin
{ calculate repulsive forces }
for v in V do begin
{ each vertex has two vectors: .pos and .disp }
v.disp := 0;
for u in V do
if (u ≠ v) then begin
{ Δ is short hand for the difference }
{ vector between the positions of the two vertices }
Δ := v.pos - u.pos;
v.disp := v.disp + (Δ/|Δ|) * fr(|Δ|)
end
end
{ calculate attractive forces }
for e in E do begin
{ each edge is an ordered pair of vertices .v and .u }
Δ := e.v.pos - e.u.pos
e.v.disp := e.v.disp - (Δ/|Δ|) * fa(|Δ|);
e.u.disp := e.u.disp + (Δ/|Δ|) * fa(|Δ|)
end
{ prevent from being displaced outside frame }
for v in V do begin
v.pos := v.pos + ( v. disp/ |v.disp|) * v.disp;
v.pos.x := min(W/2, max(-W/2, v.pos.x));
v.pos.y := min(L/2, max(-L/2, v.pos.y))
end
end

```

Where f_a denotes the attraction force and f_r the repulsive force; d represents the distance among nodes.

The constants c_1 , c_2 and c_3 were experimentally adjusted to get a good visualization of the graph (Ridao & Doorn, 2015).

The Frame

The graph must be contained within a predefined frame. The Fruchterman & Reingold algorithm puts many unmovable artificial nodes on the perimeter of the frame with no attractive forces. In this way the frame is modeled as four walls that enclose the graph within them.

Choosing appropriated values for the constants c_1 , c_2 and c_3 , has shown that such wall is completely unnecessary. Furthermore, the wall introduces unrealistic deformation on the parts of the graphs near the wall. This deformation disappears when such wall is removed.

SOLUTIONS AND RECOMMENDATIONS

Some Paradigmatic Results

Graphs were created from LELs of actual organizations for several study cases. Every one of these cases was taken from a repository of LELs ensuring that no one of the authors of this work have been involved in its creations. All of them allowed to clearly see existing clusters. Due to their relevance, three of these cases are briefly summarized in this section.

An additional precaution was taken. Each graph was created many times departing from different initial configurations. The observed result was that for each case studied the final graphs were always notoriously similar.

Case 1: No Previously Known Clusters

In this case, the graph was created with no previous review of the LEL, to ensure that there was no previous knowledge about the existence or not of clusters in the graph.

Figure 4, depicts the obtained graph. The edges were removed from the figure to improve the visualization of nodes location. The graph shows only one cluster. The subsequent semantic analysis confirmed this conclusion.

Symbols with less importance: 24, 62, 65, 32 and 44 appear in the graph in peripheral locations.

Case 2: Two Clusters Previously Known

In this case, the graph was created using a LEL which was previously studied to verify if the algorithm will confirm or not what was already known. Figure 5 presents the node distribution for this case. This Figure clearly shows the existence of two clusters. Furthermore, all the nodes are placed within the cluster to which it was supposed they belong. A few nodes interconnecting both clusters are located in the central area of the graph. This is the case of nodes 11, 50, 75, 76, 77 and 78.

Case 3: Two Clusters Previously Known

This case had the same treatment given to case 2; the graph was created using a LEL which was previously studied. This study allowed detecting the existence of two clusters. Surprisingly, the graph clearly depicted three clusters, as seen in Figure 6. To confirm this result, a semantic review was done, and it became obvious that one of the previously known clusters was made up by two different semantic nucleuses. This is the most important result since here the algorithm helped to detect invisible information.

A closer look to the graph shows that connecting nodes are located in intermediate areas close to the clusters they are connecting. Also some less important symbols are placed away from the center of the cluster to which they belong.

Figure 4. Resulting graph for case 1

Use of Indicators to Determine the Number of Clusters

At a first glance, it can be seen that there are geometric differences among the three examples above described. For the case 1 and 2 there are some symmetry of the node distribution over both

axis X and Y. On the other hand, in case 3 this symmetry does not exist.

Symmetry coefficients are:

- Case 1:

$$AS_X = 0.02 \quad AS_Y = 0.14$$

Figure 5. Resulting graph for case 2

Figure 6. Resulting graph for case 3

- Case 2:

$$AS_X = 0.05 \quad AS_Y = 0.14$$

- Case 3:

$$AS_X = 0.79 \quad AS_Y = -0.48$$

When symmetry coefficients have values rather different from 0, for at least one axis, it is very likely that the LEL under study would have 3 or more clusters. More experiments are needed to infer the limit that may make reliable this distinction.

In the case 2, the nodes are placed in an ellipsoidal pattern, suggesting the existence of two clusters. Vertices belonging to each grouping are closer to one of the focal points of the ellipse. The quotient of the variance of the coordinates distribution for each axis in this case is:

$$CV = \frac{\sigma_X^2}{\sigma_Y^2} = 3,18$$

Case 1 has a variance quotient near to 1. Again, not enough experiments have been done to infer a limit that may allow distinguishing case 1 and case 2.

FUTURE RESEARCH DIRECTIONS

In the near future, several improvements and extensions will be included in the current algorithm used for graph construction. They may be sorted as:

- **Increment in the Number of Dimensions:**
The graphs already constructed have been restricted to two dimensions due to visualization restrictions and to the cultural influence of the traditional use of graph. It has been observed, in just a few cases, that the presence of more than three clusters leads to confusing graphs. Graph used for visualization of real world problems have no reasons to be tied to two dimensions. However, three or more dimensions will bring the necessity of improved visualization techniques.

- **Change in the Visualization Techniques:**
At a first glance, there are two possible ways to improve visualization:
 - Projecting dynamically the n dimension graph over arbitrary planes.
 - Changing automatically the size, color and shape of the nodes and edges using attributes extracted from the actual origin document.
- **Applying the Technique to Other Models:**
Such as Current Scenarios, Future Scenarios and Software Requirements Specifications documents. These models are capable for being visualized using graphs.

It is also necessary a systematic comparison of this cluster construction technique with other proposals, such as Duan et al. (2009).

CONCLUSION

A strategy that helps to detect symbol groupings in the LEL has been proposed. Every one of the detected cluster in all studied cases coincide with existing functional groups in the application domain. This grouping motivates a second reading of the LEL, making easier to acquire more knowledge about the application domain.

One of the most important and unexpected features of this tool is that sometimes the discovered cluster were unknown by the LEL authors. This becomes an effective knowledge discovering feature.

The automatic construction of graph seems to be a very useful tool to visualize part of the implicit information embedded in Natural Language Requirements Engineering documents. This has been proven on glossaries and it is expected to be also true for other Requirement Engineering Process documents.

The obtained results are easily combined with several generic cluster detection strategies, which require a previous knowledge of the number of clusters; such number is one of the results of the automatic graph construction.

KEY TERMS AND DEFINITIONS

Application Domain: The context in which the software system will be used.

Drawing Graphs Methods: An area of mathematics and computer science that combines methods from geometric graph theory and information visualization to derive two-dimensional graph depictions.

Force-Directed Algorithm: A method for calculating a graph layout. It calculates the layout using only information contained within the structure of the graph itself, rather than relying on domain-specific knowledge.

Language Extended Lexicon: A glossary composed by a set of symbols, words or phrases which are peculiar and frequently used in a given application domain. The symbols included in a LEL have a different meaning than the regular use. It contains hypertext links that interconnect symbols.

LEL Graph: A graph where the vertices are the LEL entries and the edges represent the hypertext links among entries.

Requirements Engineering: An area of the Software Engineering which is responsible for acquiring and defining the needs of the software system.

Semantic Cluster: A group of terms in the Language Extended Lexicon, representing an area of interest in the business process.

Dynamic Situational Adaptation of a Requirements Engineering Process

INTRODUCTION

The adaptation of any process to particular situations is considered a good practice in most fields. Literature shows that this practice is quite common in Software Engineering processes, such as the methodologies Rational Method Composer (Haumer, 2005) and OPEN Process Framework (Firesmith & Henderson-Sellers, 2002). However, Requirements Engineering (RE) approaches are seldom tailored to context or project situations (Potts, 1995; Leite, Hadad, Doorn, & Kaplan, 2000; Leffingwell & Widrig, 2003; Seyff et al., 2009). Nevertheless, sometimes the elicitation activity, as part of an RE process, is performed taking into account some environmental characteristics, such as number of information sources, user geographical distribution, user time availability, user experience, among others (Maiden & Rugg, 1996; Hickey & Davis, 2003; Coulin, 2007; Carrizo, Dieste, & Juristo, 2008). Recently, some proposals have appeared to design an RE process for a specific project by selecting existent RE techniques (Lauesen, 2002; Lobo & Arthur, 2005; Alexander & Beus-Dukic, 2009).

There are activities of the requirements process that are invariant regardless of situational factors, while others should be modified, removed or replaced. Not only activities may be adapted, models produced or used in the process may be also suited for the situation (Galster, Weyns, To-

fan, Michalik & Avgeriou, 2014). This means that the RE process may be assembled like a flexible puzzle using interchangeable pieces depending on the situational factors identified.

Situational Method Engineering (SME) is advocated to build methods tailored to specific situations for the development of systems (Kumar & Welke, 1992). Following its principles, the adaptation of any software development process is based on indicators describing the situation (Khan, bin Mahrin & Chuprat, 2014). Part of the task is to compose such indicators based on observable factors, like degree of business processes reengineering, context complexity, developer expertise in the application domain, and project size, among others. Ideally, these situational factors should be taken into account before beginning the software process. However, there are factors not accurately known when initiating a software project, while other factors may change during the course of the project. Hence, a dynamic view of the adaptation of a software development process achieves a better effectiveness of the process itself. Considering that the production of requirements is the starting point of a software development, it should be necessary to pay more attention to factors impacting on the RE process.

A frequent question of practitioners is related with the obligation of performing all the process steps to reach requirements. *Is it possible to shorten the road or to follow a different one?* Under some

circumstances, there is an opportunity to reduce the RE process by deleting or simplifying activities; and sometimes different paths may be followed by choosing other techniques or even extending some activities. Project managers should make decisions depending mainly on the particular case.

Since problem domain knowledge is mostly expressed in natural language (NL), the use of an RE approach based on NL representations improves the commitment of customers and users to the project, increasing the probability of project success (Macaulay, 1993).

Therefore, in this chapter it is presented the tailoring of an RE process based on NL models, according to a particular set of situational factors. Additionally, a process for constructing this RE process, including the evaluation of such factors along software development life cycle, is proposed as an enhanced solution.

BACKGROUND

When working on the creation of an engineering product or system, it is important to have a process. This means having a predictable set of activities, techniques, inputs and outputs helps get a high quality outcome. Hence, the way the work is performed does not depend on individual criteria, allowing repeatability of costs, times and quality, and promoting the accumulation of knowledge about the process. As a consequence, the first activity of a process to develop a product consists in defining precisely the expected outcome. When the product is a software system, this initial activity is an RE process, whose outcome is a Software Requirements Specification (SRS). The RE process is particularly different from other activities of the software development process since it is the one that most interacts with people and their environment, while other activities are mainly carried out within the development team context (Carrizo, 2009). Besides, project decisions impose constraints, tools and methods to carry out those activities. Therefore, if the requirements

process takes into account the particularities surrounding the application context and the project itself, then it will probably result both in a better SRS and in a more effective process.

Additionally, a requirements process needs appropriate and continuous communication to gain customers and users compromise. Good communication is achieved when all stakeholders use the same language. In RE, a proven way to accomplish this is by using the vocabulary of the application context (Leite, Doorn, Kaplan, Hadad, & Ridao, 2004). Communication occurs when stakeholders orally interact, and also when reports, documents and models are exhibited to customers. In this sense, NL models, such as glossaries, use cases and scenarios, stimulate stakeholders communication (Leite et al., 2004), and are the most frequently used in RE (Kaindl, 2000; Leffingwell & Widrig, 2003; Seyff et al., 2009; Antonelli, Rossi, Leite, & Oliveros, 2012).

Software development processes put into practice in real projects are often forced to be adjusted due to contingent circumstances, sometimes in a poorly controlled fashion while the project is ongoing. Hence, the evolving situation should be observed as the process goes forward in order to achieve a better tailoring. Possible adjustments to the process can be known in advance on the basis of certain characteristics, though they may change dynamically, i.e., settings are pre-planned but only implemented when an aspect of the situation changes (Rolland, 2008). In this regard, the process is defined as a set of blocks, having process blocks common to all situations and variant process blocks according to situational factors. Thus, the process is made up by assembling blocks for the particular situation (Henderson-Sellers & Ralyté, 2010). Method Engineering was specifically created to tackle this case, promoting the design, construction and adaptation of methods, techniques and tools in order to develop information systems (Brinkemper, 1996). This discipline considers not only the creation of process blocks but also product blocks, and even blocks that assemble both process and product (Rolland, 2008; Henderson-Sellers &

Ralyté, 2010; Ralyté, 2013). Rolland (2008) not only has pointed out that the software development should begin with a definition phase of the method to be used, but also she proposes that the process must be re-adjusted throughout the life cycle process, an aspect not treated by Method Engineering. SME, as a sub-area of Method Engineering, focuses on building methods for software development, tailored to specific situations (Kumar & Welke, 1992). Thus, SME studies the factors affecting the software project and the application context (Bucher, Klesse, Kurpjuweit, & Winter, 2007). Its principles have been applied in RE to define requirements processes that are adaptable to particular circumstances by using existent modular components (Firesmith, 2004; Jafarinezhad & Ramsin, 2012; Bakhat, Sarwar, Motla, & Akhtar, 2015).

Some of the adaptation factors are related to development time constraints. Naturally, they lead to faster ways of developing software; these are steps toward agile methods (Pinheiro, 2002). A quality factor may depend on a time factor, or the other way around. However, a balance equation for both factors may be frequently achieved (Kohler & Paech, 2002; Pinheiro, 2002). This trade-off is more likely to be better faced by an RE process with the necessary tailoring (Kohler & Paech, 2002). Extremely, when time factors are a major concern, agile methods could be the best way. Though, agile practices are frequently assumed as opposite to RE practices (Cockburn, 2002; Beck, 2004), Kovitz (2002) remarks that both, a phased development and an agile one, do RE but in different styles, since requirements are always present. This vision is also shared by (Sillitti & Succi, 2005; Kohler & Paech, 2002). In this sense, an agile approach dealing with requirements may be also seen as a sort of dynamical adaptation of an RE process. As Cockburn (2002) said, making the decision on the right level of agility is the best way to succeed on a project. RE practices do not deny agility, considering that this property must be combined with quality and attending volatility without constant software fix (Pinheiro, 2002).

A REQUIREMENTS ENGINEERING PROCESS ADAPTABLE TO SITUATIONAL FACTORS

RE process based on NL models strongly contributes to stakeholders' commitment to the project. It involves the following stages:

- *Defining the general software goal and scope.*
- *Understanding the vocabulary used in the application context*, supported by the Language Extended Lexicon model (Hadad, Doorn, & Kaplan, 2009).
- *Understanding the application context*, supported by a set of current scenarios that represent the situations observed in the application context (Leite et al., 2000).
- *Refining the general goal*, by decomposing it into sub-goals.
- *Defining the software context*, by producing a set of future scenarios that represent situations envisioned in a future application context where the software system will operate (Leite et al., 2004).
- *Defining the vocabulary used in software descriptions*, by producing a Language Extended Lexicon of the System created from the previous one, adding terms used in the descriptions of future scenarios.
- *Making explicit the requirements*, by producing an SRS, after extracting requirements from future scenarios.

This RE process has been initially developed and used in a monolithic fashion, as depicted in Figure 1(a), being independent of any special circumstance. Most main sub-processes are composed of another level of processes, some of which are atomic processes while others are decomposed, as it is shown in Figures 1(b) and 1(c). Recycles in the three diagrams were removed to emphasize the variation points. These recycles imply correcting or updating models as a consequence of a better understanding of

Figure 1. Basic Requirements Engineering Process with two main sub-processes

the problem and of the evolution of the application context.

Though Figure 1(a) shows a monolithic process as part of a cascade model, the strategy can be adapted to be used within different software process models, being this a project factor by itself (see Table 1). For instance, when following an iterative process model, the RE process is performed sequentially for the first four main sub-processes and the last three sub-processes are usually done in iterations along with a requirements change management activity throughout the software development life cycle. It should be noticed that in some cases the fourth sub-process may be included in some of the iterations. Iterations obey to a prioritization activity

within *Software Goal Refinement* sub-process. In an incremental process model, requirements are initially produced, and iterations are based on those defined requirements, obviously allowing requirements evolution. Under this process model, the entire RE process is performed as the starting point, though requirements change management occurs along development life cycle. Regarding agile practices, additionally to time constraints, another leading factor is volatility (Cockburn, 2002), which may be well coped with a change management activity. Though, it may not be the best manner when volatility is a core characteristic of the context. Therefore, an agile method might be a better proposal to satisfy customers in the meanwhile.

This basic RE process may be adapted at the variation points shown in Figure 1(a), depending on a combination of situational factors. Project managers should do it to improve the RE process and, thereby, the requirements product. Situational factors impacting on RE (see Table 1) have been selected based on experience in RE practice and literature proposals (Maiden & Rugg, 1996; Hickey & Davis, 2003; Carrizo et al., 2008; Jafarinezhad & Ramsin, 2012). These factors can be characterized by the following attributes:

- **Value:** Admissible values depend on each factor.
- **Confidence on the Value:** High, Medium, Low.

- **Origin Type:** Application Context or Project.
- **Evolution Type:** Invariant or Contingent.
- **Variation Points:** Where it impacts on.

In order to adapt the RE process, project managers assign values to factors, qualifying them with their degree of confidence on such values. It usually happens that at the very beginning some factors may be not precisely known, since right values are known after gaining a better understanding of the situation. Factors are classified according to their origin into: those related to the specific application context, and those related to the specific software project. From an evolution dimension, factors are classified into: *Invariant*, being those

Table 1. Situational Factors impacting on RE process. Range Very High to Very Low includes five possible values.

Context Factors	Acceptable Values	Evolution	Variation Points
Context Complexity	Very High to Very Low	Invariant	2,3
Target Customer	Tailor-made, Market-driven	Invariant	1,2,3,4
New Business	Yes, No	Invariant	1,2,3,4
Business Process Reengineering	Very High to Very Low	Contingent	3,4
Context Volatility	Very High to Very Low	Invariant	2,3
Volatility of Customer Demands	Very High to Very Low	Contingent	2,5
Users Rotation	Very High to Very Low	Invariant	2,3
Context Inconsistencies	Very High to Very Low	Invariant	2,3
Conflict of Users Interests	Very High to Very Low	Contingent	2,3
Project Factors	Acceptable Values	Evolution	Variation Points
Familiarity with the Domain	Very High to Very Low	Contingent	1,2,3,4
Size of the Project	Very High to Very Low	Contingent	2,3,5
Developers Rotation	Very High to Very Low	Invariant	2,3
Software Quality Required	Very High to Very Low	Invariant	1,2,3,4,5
Reuse existing Requirements Artifacts	Yes, No	Invariant	1,2,3,4,5
Creating Requirements Artifacts for Reuse	Yes, No	Invariant	1,2,3,4,5
Requirements Pre-Traceability	Yes, No	Invariant	1,2,3,4
Requirements Post-Traceability	Yes, No	Invariant	5
Granularity of Requirements Traceability	Individual, Group	Invariant	5
Demand to produce an SRS	Yes, No	Invariant	5
Project Time and Resource Constraints	Very High to Very Low	Contingent	1,2,3,4,5
Software Process Model	Cascade, Incremental, Iterative, Agile	Invariant	1,2,3,4,5

that do not change during the RE process; and *Contingent*, being those that may naturally evolve due to changes in the application context and/or in the project context.

Interaction among factors should be taken into account when tailoring the RE process. *Overriding interaction* indicates that a factor is discarded when another factor takes a specific value. *Limiting interaction* points out that a factor may reduce the range of acceptable values of another factor. *Incompatible interaction* implies that the values of two or more factors cannot be accepted simultaneously at the same project; thereby, the value of at least one factor has to be changed through stakeholders' negotiation to solve the inconsistency. Examples of these interactions are:

- **Overriding Interaction:** The factor Business Process Reengineering is not taken into account if the factor New Business takes the value *Yes*.

- **Limiting Interaction:** The factor Software Process Model cannot take the value *Cascade* if factor Context Volatility is *Very High*.
- **Incompatible Interaction:** The factor Software Quality Required is *Very High* while the factor Project Time and Resource Constraints is *Very Low*.

Each sub-process is defined by a sequence of process blocks, some of which include product models. At each variation point a basic process block may: i) stay as it is; ii) be deleted; iii) be replaced by a particular process block; or iv) be replaced by a process block with a partial internal variation based on parameters. Figure 2, exploiting sub-process of Figure 1(c), shows how the instance of a process should be constructed according to specific situational factors, using a repository containing all possible atomic blocks. This Figure exemplifies two process blocks that may be deleted (*Scenarios Organization* and *Sce-*

Figure 2. Defining the Future Scenarios Construction Sub-Process

Table 2. Valid operations on atomic process blocks

BLOCK TYPE	OPERATIONS			
	Stay	Delete	Replace	Parameterize
Own	✓	✓		✓
Shared	✓	✓		✓
Variant		✓	✓	

narios Verification), a process block that should be replaced by one of five different atomic processes (*Future Scenarios Outline*), two process blocks that are parameterized (*Scenarios Verification* and *Scenarios Validation*), and a process block that stays independently of any factor (*Future Scenarios Description*).

There are common elements among the various parts of the RE process. For example, Figure 2 shows two process blocks *Scenarios Organization* and *Scenarios Verification* which both are shared with another main sub-process *Current Scenarios Construction*. There are four types of atomic process blocks. An *own block* is that not shared

Figure 3. Instance of the RE Process for a specific situation

Figure 4. Evolution of the Instance of the RE Process

by any other main sub-process and is independent of situational factors. A *shared block* is common to different sub-processes of the RE process, and may depend on factors. A *variant block* belongs to a specific sub-process and depends on situational factors. A *null block* is an auxiliary block used when an entire sub-process or an atomic process must be deleted or skipped from the basic RE process. Table 2 shows operations that may be applied to each type of process block.

Some process blocks include product blocks, which contain minor variations of the NL models produced by the RE process. For example, if the lexicon model is not created, then the scenario

model does not include hyperlinks to lexicon symbols.

Figure 3 shows an instance of the RE process constructed for a specific situation, which is represented by a set of values given to factors at the beginning of the project. Those factors are sketched at the bottom of this Figure. While ongoing the project, some factors may evolve or change; this is exemplified in Figure 4 where at variation point 3 (see Figure 1), the following factors were updated: Business Process Reengineering, Users Rotation and Demand to Produce an SRS. These three factors, along with some others, gained a better confidence. The first and the third factor

have impacted on two different sub-processes, thus Figure 4 shows only sub-processes requiring a re-design.

SOLUTIONS AND RECOMMENDATIONS

The adaptation of the basic RE process involves the application of a mechanism of operations on process blocks at every variation point, using a specific combination of situational factors, following SME principles. The variation points are milestones to review the RE process and to indicate possible re-design of remaining RE activities. The process for constructing the RE process for a specific situation includes the following activities (see Figure 5):

1. **Factors Set-Up:** The situational factors are evaluated, assigning a degree of confidence to each value, and taking into account the interaction among factors. A simple form is used to collect the factors value. This form eases its filling with valid values by means of rules for factors interaction.
2. **Analysis:** The factors setting is analyzed considering mainly interactions and factors with low confidence. Project managers should take a position on every factor with low confidence: optimistic, conservative or balanced position. Under an optimistic position, factors are assigned an extreme value of its valid range depending on the meaning of the factor, while under a conservative position factors take the opposite extreme value. A balanced position involves choosing intermediate values. This re-allocation of values is done to allow assembling the process, since the original values are preserved. When incompatible interactions are observed, a negotiation must take place.
3. **Negotiation:** The purpose of this activity is to reach an agreement among stakeholders to re-assign values to incompatible factors.

4. **RE Process Assembly:** The RE process is assembled departing from the basic process, considering a subset of situational factors at each variation point (see Table 1, last column). A set of rules based on a specific combination of those involved factors defines which operation is applied over each basic process block (see an example at Figure 2, right part). Thus, this assembly activity consists in maintaining, deleting, replacing, or parameterizing process blocks.
5. **Factors Re-Evaluation:** At every variation point, those factors involved in remaining variation points must be re-evaluated. Low-confidence factors must be watched, since its level of confidence is supposed to increase due to a better perception of the situation. Contingent factors must be also watched to establish if a change in the situation has occurred. After this activity, a new factors analysis is needed in order to ensure the absence of inconsistencies among dependent factors.

Figure 5. Process for Constructing an RE Process, based on situational factors

Since requirements are the foundations for a good software product, an RE process is crucial to the project success. Project managers should take decisions about selecting the appropriate RE process for a specific situation. A way to define the situation is by its characterization through context and project factors. Therefore, project managers should define as precisely as possible those situational factors in order to construct the suitable RE process. However, they should be aware of the potential evolution of the situation and, thereby, review factors and adjust the RE process at pre-defined milestones.

FUTURE RESEARCH DIRECTIONS

Feasible variants of the process were identified due to the experience achieved after putting into practice the basic RE process in many real cases along two decades.

Situational factors were exhaustively studied in literature, although this set is likely to be extended. Factors impacting on subsequent phases of the software development process will be studied to determine if they may influence backward on the RE process.

The decomposition of the RE process in basic process blocks, along with the set of situational factors, has allowed identifying process commonality and process variability, and hence defining the different types of process blocks needed. It is planned to evaluate the convenience of using mixed blocks, or separated process blocks from model blocks. It is also considered that more cases should be done to confirm the different branches of the adaptable RE process.

CONCLUSION

The proposal presented in this chapter deals with variability in an RE process, driven by a dynamic adaptation based on prevailing situational factors.

Most problems have distinctive features that must be taken into account to carry out a successful requirements process. Project managers should tailor the requirements process by choosing the techniques that are most suitable for specific situations. When they are provided with guidelines on how to adapt the requirements process, they are more willingly to do it.

The process for constructing an RE process involves a set of factors that typifies situations considering both the application context and the software project context. This adaptation process establishes when the RE process should be reviewed and re-tailored based on rules and operations at each variation point. Since it is frequently observed the natural and contingent evolution of situations, it is important to have the possibility of redefining the remaining activities of the RE process once the project is in course.

The adaptation of the requirements process for several real cases has contributed to its acceptance in host organizations. It is considered that the dynamic adaptation process could be implemented with minor adjustments in other RE strategies.

KEY TERMS AND DEFINITIONS

Process Block: A well-defined unit of process that can be reused as part of any process.

Process Commonality: The common elements of a process that facilitate the definition of a family of processes through reuse.

Process Variability: The variant elements of a process, identified at variation points, which produce deviation from the standard process.

Requirements Engineering Process: A process to produce software requirements by means of methods, techniques and tools during elicitation, modeling, analyzing and evolution of requirements.

Scenario: A representation of an observed or envisioned situation in the application context.

Situational Factor: A characteristic of the project or the application context that may be taken into account when implementing an RE process.

Situational Method Engineering: A discipline that promotes the construction of methods for developing systems according to a pre-defined set of situational factors.

A Formal Approach to the Distributed Software Control for Automated Multi-Axis Manufacturing Machines

S

Gen'ichi Yasuda

Nagasaki Institute of Applied Science, Japan

INTRODUCTION

Nowadays complex automated machinery is composed of multiple independently-driven subsystems, where each subsystem is actuated by at least one effector. The evolution of an overall system is not represented by time but by events, called discrete event based state change systems as a new type of dynamic systems. Typical discrete event systems, which are essentially manmade, include computer operating systems, communication networks, traffic control systems, service systems, and manufacturing systems, especially Flexible Manufacturing Systems (FMS) and Computer Integrated Manufacturing Systems (CIMS). Modern automated intelligent machinery also has the same features as such innovative discrete event systems. In the most part of such systems, the nature of the subsystems is asynchronous and their behaviors are concurrent, independent of other subsystems. During execution of an activity of a system, each subsystem assumes its own unique state without knowledge about the state of other subsystems.

In such a naturally distributed hardware structure, independent axes should be synchronously activated according to events required for cooperative task execution. When activities that depend on some resources are required, the subsystems have to communicate in order to update their status and to synchronize their actions. When two activities needing a shared resource are waiting for the end of the other activity, it may be resolved according to the operational constraints with priority. Different negotiation techniques between subsystems which should cooperate can be adopted based on

distributed communication structures, such as a variety of modified client/server protocols where the client and the server are not fixed, such that they are dynamically chosen according to the status of each in the system. Otherwise, a symptom of deadlock is detected and any supervisory function should be triggered based on centralized communication structures, so that, through any centralized decision making, the resource is assigned to one activity.

This chapter presents a unified and systematic design methodology of discrete event distributed control architecture by embedding intelligent agents with Petri nets. A machine-oriented, agent-based modular distributed software system is configured on a hierarchical distributed microcontroller based hardware structure for real-time intelligent machine control (Yasuda, 2010; 2011). The design of functionally distributed control software for real-time cooperative task execution is described based on the hierarchical modeling of machine tasks. Based on Petri net models of hardware elements of sensor devices such as switches, a set of program modules to execute primitive actions of effectors, is integrated with hierarchical and distributed configuration of behavior and control agents, especially to attain the synchronization of multi-axis motions involved in the complex manufacturing task.

BACKGROUND

Petri nets and automata are the most used to describe discrete event system control. Modeling and

DOI: 10.4018/978-1-5225-2255-3.ch647

analysis of discrete event systems with controllable and uncontrollable events, turned on and off by the supervisor, were proposed based on automata theory (Ramadge & Wonham, 1987). However, finite automata present some drawbacks such as the difficulty to model parallelism, synchronization and resource sharing. Although control commands generation was related to state transitions, since the connection of several finite automata is no longer a finite automaton, the communication specifications between modules can not be achieved using the finite automata framework (Lima & Saridis, 1996; Stadter, 1999; Silva et al., 2014). In spite of a great number of researches concerning advanced methods and tools to analyze the distributed models, these models are mostly constructed by empirical methods based on the knowledge of experts and customized for a particular application. Most approaches are limited by the combinatorial explosion that occurs when attempting to model complex systems.

On the other hand, Petri nets incorporate the notion of a distributed state of a system and a rule of state change (Murata, 1989; David & Alla, 1992), providing a mathematical formalism and a graphic tool for the formal representation of a system whose dynamics is characterized by concurrency, synchronization, nondeterministic decision, mutual exclusion and conflict. Computerized automation systems have the same, typical and most important features as industrial distributed systems.

As a mathematical formalism, a matrix equation can be set up to perform structural and behavioral analysis (Wisniewski et al., 2014) using a formal state-space representation. A Petri net simulates the behaviors through the flow of tokens like a flow chart, providing a visualization of the dynamic system. Petri nets allow a modular and hierarchical synthesis approach (Gomes & Barros, 2005) which can build up Petri nets from specification languages or formal definitions to control code. The ultimate goal of the development of Petri nets is to provide a methodology for control system design that is able to cope with the most dif-

ficult and important aspects of non-deterministic cooperative control (Yasuda & Tachibana, 1991). Thus, the Petri net approach is expected to improve the performance of software control of multi-axis machines in automation systems.

FORMAL APPROACH TO CONTROL SYSTEM DESIGN BASED ON PETRI NETS

In control system design, model based and non-model based are two common approaches. Model based approaches use a model of the process under control for synthesis and verification to derive a controller based on formal specifications, whereas non-model based approaches have minimal or no assumptions about the process under control. The proposed methodology for embedded control system design using hardware-software co-design techniques starts with the description of the system's functionalities through a common system specification language such as Unified Modeling Language (UML). Then the description is translated into a set of formal models using hierarchical Petri nets as the reference model formalism.

At the highest level, the models represent system requirements, independent of any specific implementation platform. At the intermediate level, the models reflect the specific characteristics of system construct. These models are amenable to be translated into code, by being decomposed into sub-models and mapped into specific local controllers. The model based approach assures that a correct model at the highest level maintains its correctness, independently of selecting different mapping and implementation techniques. At the lowest level, the code reflects the concrete syntax of a specific implementation platform. For the model transformations between different abstraction levels, hierarchical Petri nets can be used, although any other behavior formalism with similar characteristics may be used without loss of generality of the proposed methodology.

Figure 1. Generalized flow of Petri net based control system design

The flow of control system design is shown in Figure 1. First the global system model is implemented as a centralized controller. Next, using model decomposition, several sub-models for independent controllers are obtained and implemented in the same platform. Finally the sub-models are implemented in different platforms or local controllers, such as microcomputer based systems, Programmable Logic Controllers (PLCs), etc. Behavioral properties associated with the execution of the distributed models are compared with the execution of the initial centralized model.

An ordinary Petri net is a weighted bipartite defined by a quadruple: a finite set of places represented by circles, a finite set of transitions represented by bars or rectangles, the flow rela-

tion of arcs connecting places and transitions, and the weight function which associates a nonzero value to each arc. Tokens reside in the places, represented by solid circles or dots, and a marking assigns to each place a positive integer, indicating the system state as a marking vector.

In condition-event Petri nets, where the weight value associated with an arc is 1, a condition that can be either true or false is represented by a place and a token. Events that can occur are represented by transitions. An event is enabled, or can fire or occur, if and only if all its pre-conditions are true and all its post-conditions are false.

A Petri net can be refined hierarchically by putting a subnet in a place and/or a transition. The subnet is subordinated to the higher-level place or transition. Unfolding is done by replacing the hierarchical net with a structure putting the corresponding subnet in parallel to the higher-level element as shown in Figure 2. A subnet definition should be self-contained without taking the other elements of the hierarchical net into account, while the subnet should not influence the outputs of the hierarchical net, so that the behavior of the flat net is identical with the hierarchical net.

SYNTHESIS OF HIERARCHICAL DISTRIBUTED NET MODELS FOR MACHINE TASK EXECUTION

Since Petri nets are a generalized and uninterpreted technique to represent discrete event systems, for modeling a specific system, an interpreted form of the Petri net is necessary to clearly model the functional features of the system including the required control conditions. From the view of discrete event systems, the dynamic behavior of a manufacturing machine is considered as the flow of discrete activities with the control of their start/end events between two successive activities. A machine activity means a manufacturing process performed in a workplace for objects (workpieces, parts or products), such as moving, mechanical processing, assembling, disassembling, buffer-

Figure 2. Hierarchical net modeling for real-time task control: (a) hierarchical control by dynamic subnet invocation and (b) its equivalent form with parallel construct

ing, etc. and can be seen as a task, operation or action according to the level of abstraction in the manufacturing system. A task is decomposed into a successive set of operations and actions, which also correspond to detailed processes for objects.

Typically, a workplace indicates a place where objects can be temporarily and stably held or stored for a specified manufacturing process. The condition for the execution of a process activity to start is the arrival of all specified objects and resources in the workplace, and the result of the process is one or more objects in the next workplace and the release of associated resources. A task flow graph is composed of workplaces and directed connection arcs between workplaces, representing the flow of manufacturing processes.

For explicit description of input/output facilities, the Petri net is extended to control the net model execution through transition firing using special input/output arcs in response to its environmental situations based on signal instead of events. A set of input signals, a set of output signals, a mapping associating every transition with a firing condition, or a Boolean function in the set of input signals, and a mapping associating

every place with an output function in the set of output signals, are specified.

A signal source or external device is represented by a macro place in the environment, which represents a subnet model of the corresponding hardware device. An enabled transition fires immediately when its firing condition associated with a combinatorial logical function is fulfilled. By addition of timing conditions, periodic, delayed or spontaneous firing of transitions can be adopted for autonomous machine control.

In automated manufacturing systems, subnets can be easily identified which realize certain subtasks performed by one machine or effector. A higher-level automation can be achieved through the specification transformations. The expected benefits of using a hierarchical model based approach for generating the models and respective code is to lower the cost of deploying a component and its code on multiple platforms or controllers through reuse. The hierarchical structure of machine control in a manufacturing system is conceptually composed of three levels from lower to higher: action level, operation level and task level. The lower levels are provided as

one of the sublevels determined by the upper level. In manufacturing systems, a machine or system is composed of units, and a unit is composed of devices, where each level is controlled based on sensing and actuating information with a corresponding level of abstraction. At each level, control specifications are represented using Petri nets and associated to corresponding resources required for real-time execution. For multi-axis machines, the action level is concerned with the actions executed by individual effectors. Because an action is executed by an associated effector in its workplace, if two actions are executed by a same effector, access to the workplace is in mutually conflict as a shared resource. The operation level is concerned with the operations executed by several effectors, where the objective is explicitly described by operation programs. At the task level, the discrete event systems representing machine tasks are concretely evaluated as task specifications.

Based on the proposed formal approach, the Petri net based control specifications are designed according to the levels of machine control. First, a task flow graph is defined as a conceptual net model for control specification at the task level, which describes the flow of objects through the machine process and availability of resources (machine units) using high-level Petri nets, where places represent the status of objects and resources. A task involves an object and at least one resource. Each object or resource can be either idle or involved in a task. Identification of the necessary tasks and related resources should be done using a database and/or based on online environment monitoring.

Due to the physical capacity of the machine units, such as assembling, disassembling and transfer devices, or operational limits, the maximum number of objects that can be accepted in the workflow section is prescribed. The restrictive condition is represented through a dummy place with limited capacity connected between the initial and final transitions of the section. Alternatively, inhibitive signal arcs are connected

in the initial transition of the section. The above control conditions are realized as a coordinator at a higher level in the hierarchical net model. A message sending/receiving mechanism based on asynchronous communication allows levels to communicate by taking control and monitoring requirements into account.

At the task level, the whole net model is split up into several sub-models which represent all possibilities of state change of a resource and all relations with other resources. Since the operation level comprises the detailed net models of activities that perform a task at the task level, the task model is detailed into the subnet models which describe causal relations of operations by units in the machine. Thus, a clear view of machine controller's functionalities is provided as rules of reactive input/output conditions relationships seen from the control system. The resultant model should have a structure where the state returns to the initial condition when the specified operations are finished; a Petri net graph with this property is necessarily live or deadlock free. Due to simplified functional descriptions, the whole discrete event manufacturing process performed by a machine can be naturally considered in terms of operations and actions.

Besides a single operation, operations can be combined as a sequential or concurrent construct. In a concurrent construct, operations can coexist in the execution state with a capacity, which start and end their execution through common initial and final events respectively. Several operations (actions) are joined, such that they start separately and finish their execution simultaneously through one final event. Operations (actions) are dispersed such that they start simultaneously through one initial event and finish their execution separately. The above most common types of operations are identified using appropriate firing rules with input signals as basic types. Other types of operations can be represented as combinations of these operations.

Since machine tasks generally involve several operations mutually related, typical problems are

synchronization of operations executed in parallel and/or in conflict (Luo & Zhou, 2014). Because the net model of the whole system is composed by live sub-graphs which describe the contents of the operations, the nature of the system is determined in terms of the structural interrelations between the operations, or due to some appropriate initial marking. When operations are executed in parallel, frequently it involves the synchronization of the start and/or end of some actions. Synchronous action is modeled through the fusion of the transitions that represent the start/end of the corresponding actions. In case of shared resource, since there exist convergence or ramification in the workflow, the starting and/or ending of several operations in conflict should be arbitrated.

For real-time control at the operation level, an operation is represented by one macro place with one input transition and one output transition which correspond to the start and end of its execution, respectively. The macro place represents the progressive status of the operation by the presence or absence of the token in the place. The function of each operation needs to be represented more explicitly and precisely by adding an interpretation with practical control information.

Finally the action level describes all the details regarding input/output signal changes and variables in lowest level elements, or devices such as sensors and actuators, to execute primitive actions. Because a simple action is a single combination of outputs, each action is activated by one or more triggers. For the execution of a primitive action by a PLC, the transition, input places which trigger transition firing and output places which represent firing effects are denoted as logic variables and directly arranged in a respective ladder diagram segment. The Petri net approach significantly simplifies the construction and validation of the control system, by algorithmically building the net models and automatically translating into a program in a common PLC language, such as ladder diagrams (Milik & Hryniewicz, 2012; Peng & Zhou, 2004; Wisniewski et al., 2011).

Actions with different control laws may require the same resources (sensors and actuators) or functional procedures, simultaneously. The start of an action engages resources necessary for its execution which are restored at its completion, as indicated by arcs between the action and the resources. In these cases, some external logic circuit, called an arbiter, is introduced to solve the conflict through the connections of input signal arcs between the conflicting transitions and the sub-graph that realizes the arbitration rules.

DESIGN OF NET BASED CONTROL SPECIFICATIONS FOR AUTOMATED MACHINES

An implementation example is a mechanized hand-stretched fine noodle producing machine, which automatically performs noodle stretching with holding and expanding units and transfers the bundles to the drying process with picking and placing devices for automatic handing over. Up/down movements of the units are controlled by position feedback using rotary encoders with a speed-controlled induction motor, and start/stop motions of the devices are controlled by specified infrared sensors. The whole task starts by carrying in the machine a set of bundles with a separate induction motor. After the completion of stretching process, the set of bundles are delivered to the drying process through the transfer machine.

The transfer machine performs the transfer of a set of noodle bundles from the preceding stretching and expanding process to the succeeding drying process. Because the number of bundles from the preceding process is different from that delivered to the drying process, three conveyors to regulate the transfer speed are configured, composed of an input, an intermediary, and an output conveyor. A remote infrared sensor to detect the presence of a bundle is attached to each outlet position of the preceding process and the three conveyors, S0, and S1, S2, S3 from input to output as indicated in Figure 3. Each conveyor is enabled when there

Figure 3. Task flow graph of sequential transfer composed of three conveyors with buffers of different capacities

is a bundle in the conveyor and the succeeding conveyor is not full. The remote sensors are used to activate or stop motors to drive conveyors, in order to prevent collisions of bundles during the transfer process. The task flow graph is shown in Figure 3.

For example, when the ready signal from the preceding process is received, if S1 is OFF then the input conveyor is activated and intermediary conveyor is stopped until the buffer of the input

conveyor is full. When the buffer is full or S1 is ON, the intermediary is activated to transfer cooperatively with the input conveyor. When S1 is OFF, the intermediary conveyor is stopped, and the input conveyors may be continued according to the capacity of the input buffer. Then when the S2 is ON, the output conveyor is activated to transfer cooperatively with the intermediary conveyor, and when S2 is OFF, the output conveyor is stopped. The above control conditions and rules are

Figure 4. Detailed net model of sequential transfer machine composed of three unit controllers

represented by an extended Petri net model with different capacities in places representing conveyor actions and trigger functions for transition firing.

For the net model represented as the task flow graph at the task level, the detailed net models of the three transfer units at the operation level are shown in Figure 4, which represent sequentially connected transfer units. Because two neighboring units should be synchronously activated in order to transfer a bundle of noodle, mutual synchronization is realized by asynchronous communication, as shown with a shared place between two units. Distributed execution of the Petri net model is achieved through model decomposition into partitioned subnet models, each controlled by unit controllers.

The whole net model is decomposed into subnet models at the operation level, which are assigned to each unit controller on a microcomputer-based control system with expanded digital input/output interfaces. The task level net model is executed as the main background process, and the operation net models are executed as interrupt handling routines. The global event information necessary for synchronization and conflict resolution is processed as shared variables, which can be accessed by interrupt routines. Based on interrupts

from specified sensors, such as limit switches and encoder counts, transition enabling and firing tests at the lowest action level are executed quickly. After the transition firing, corresponding digital signals are outputted immediately through the interface.

The views of the combined noodle producing and transfer machine and the microcomputer based controller is shown in Figure 5. Although the machine cycle time depends on the number of specified events, under the conditions of ordinary slow motion speeds, the control software of the unit controllers have been satisfactorily executed with fewer states and request/response transmissions. The man-power of software development as well as coded lines could be drastically reduced compared to those written in a common programming language on a common PLC (Globelna et al., 2014). For comparison non-hierarchical Petri net model of a traditional control program for the transfer machine is shown in Figure 6. Because the hierarchical net model can reduce the number of net elements at each level, it greatly simplifies analysis and validation of the controller.

The limitations of the present work are more due to the status of the implementation than the fundamental ideas, for example due to the hard-

Figure 5. Overview of the automated noodle producing machine: (a) overall experimental system, (b) microcontroller based multi-axis sequential controllers

Figure 6. Non-hierarchical net model of control program flow of sequential transfer machine

ware and low-level software such as inter-process communication. Because the three activities (task, operation, action) should run in parallel in order to insure reactivity at every level, communication speed between levels using shared memory is also another important limitation of multithreaded implementation on a single processor. The knowledge bases required for improved robustness and better management of conflicts at every level should be optimally organized using customized retrieval software.

In contrast to the multithreaded implementation, the synchrony paradigm by synchronous communication does not apply in implementation platform of the distributed model on different time regions without a global clock. Based on an asynchronous communication scheme, a communication channel between controllers is

directed, such that an output event is generated by the master transition firing, which is read as an input event by the slave transition, where the delay is represented by a place between the master transition and the slave transition.

FUTURE RESEARCH DIRECTIONS

Some advanced agent technologies can be adopted for further development of the software control of sophisticated manufacturing machines. Because a Petri net based formal approach decentralizes the control activities for complex motion tasks, it can provide basic autonomy to agents according to a hierarchical design methodology. The task model is decomposed into subtasks in such a manner that every subtask may be assigned to an agent.

This decomposition is achieved by a partition of the centralized, functional net model, where each sub-model involves one agent controlling at least one effector. An agent acts as a decision unit when negotiating with higher-level agents, at the same time considered as a system when controlling and coordinating its components. The concepts of object-oriented programming may be applied to intelligent agents, as autonomous entities that have choices and control on their behavior, for integration of modeling, simulation and control software. The agent-based Petri net approach can be integrated with some intelligent control approach such as neural nets, for the activities related to diagnosis and error recovery or exception handling to react to unexpected situations.

CONCLUSION

Based on the formal approach using Petri nets, main control problems for automated multi-axis machines have been identified, such as synchronization, resource allocation and conflict arbitration, to assure that the resultant overall distributed control software is well-designed, coping with the prominent features of asynchronism and concurrency of complex manufacturing processes. The purpose of the formal approach is to facilitate the specification, validation, and generation of discrete event control code by smoothing the transition from specification to implementation. Three levels of detail used to describe the automated manufacturing process, offers a structural technique with well defined steps. Owing to the separation of detailed control, coordination and supervision, the task-level controller deals only with the group of command-level operations for coordination, while the implementation of primitive operations can be grouped into a single control-level macro-action performed by the local controllers. Because each level is concerned with small portions of information at a time without the need to look at all system states, the approach produces notable reduction in the number of con-

sidered states, therefore reducing the complexity of control system design.

KEY TERMS AND DEFINITIONS

Deadlock: In parallel control systems, a situation where two or more actions are each waiting for the other to finish and thus neither ever does. The liveness of the system implies deadlock-freeness.

Discrete Event Systems: A dynamic system where the state evolution depends entirely on the occurrence of asynchronous discrete events over time, consisting of discrete state spaces and event-driven state transition mechanisms.

Formal Methods: Mathematical techniques for the development of functional specifications and designs of real-time software.

Manufacturing Machines: Complex, high-speed machines which process and combine materials as they move through the machine to produce a finished product.

Multi-Axis Mechanisms: Mechanisms which have complex motion requirements by multiple independent drives, in place of the traditional centralized cam-actuated mechanisms.

Software Control: Control of electro-mechanical actuator system, where the actuator function is defined by software and can be readily modified or reprogrammed.

Synchronization: In multiprocessing systems, joining multiple independent processes in order to reach an agreement or commit to a certain sequence of actions.

Model-Driven Software Modernization

INTRODUCTION

Most vital software systems in companies have been developed several years ago with technology that today can be considered obsolete and unaligned with their current strategic objectives. These legacy systems play a central role in the company's information system. They are often large business-critical applications that have involved the investment of money, time and other resources through the years. Therefore, companies are facing the problematic of having to modernize or replace their legacy software systems.

Unlike the maintenance, software modernization involves significant changes in the structure and functionality of a legacy system with the aim of increasing its strategic value. Software modernization, understood as technological and functional evolution of legacy systems, provides principles, methods, techniques and tools to support the transformation from an existing software system to a new one that satisfies new requirements. It is related to reverse engineering, restructuring, forward engineering and reengineering processes. The definitions given by Chikofsky and Cross (1990) for these processes are still in force beyond the technological evolution:

- *Reverse engineering* is the process of analyzing a subject system to identify the system's components and their interrelationships and, create representations of the

system in another form or at a higher level of abstraction.

- *Restructuring* is the transformation from one representation form to another at the same relative abstraction level while preserving the subject system's external behavior (functionality and semantic).
- *Forward engineering* is the traditional process of moving from high-level abstractions and logical, implementation-independent designs to the physical implementation of a system.
- *Reengineering* is the examination and alteration of a subject system to reconstitute it in a new form and the subsequent implementation of the new form.

The term *Refactoring*, introduced by Martin Fowler, defines a special kind of restructuring in object-oriented code (Fowler, 1999). One of the advantages of software modernization versus traditional software reengineering is that the former allows discovering and refactoring object-oriented models at a high level of abstraction, such as business process models.

Software modernization faces many challenges due to the proliferation of new technologies such as mobile computing and cloud computing. Thus, novel technical frameworks for information integration and tool interoperability are needed. The *Model Driven Development* (MDD) appears to be an interesting approach to address these chal-

lenges since it provides principles and techniques to represent software systems through models at different levels of abstraction. MDD refers to a range of development approaches based on the use of software models as first class entities. The most well-known realization of MDD is the OMG standard Model Driven Architecture (MDA) (MDA, 2016). The outstanding ideas behind MDA are separating the specification of the system functionality from its implementation on specific platforms, managing the software evolution from abstract models to implementations increasing the degree of automation of model transformations and achieving interoperability with multiple platforms, programming languages and formal languages. The essence of MDA is the Meta Object Facility Metamodel (MOF) that allows different kinds of software artifacts to be used together in a single project (MOF, 2015). Models play a major role in MDA which distinguishes Computation Independent Model (CIM), Platform Independent Model (PIM) and Platform Specific Model (PSM). Some authors also distinguish Implementation Specific Model (ISM) as a description (specification) of the system in source code. To express transformations, OMG defined the MOF 2.0 Query, View, Transformation (QVT) metamodel (QVT, 2015).

OMG Architecture-Driven Modernization Task Force (ADMTF) is developing a set of specifications and promoting industry consensus on modernization of existing applications (ADM, 2016). In the ADM context, software modernization can be summarized as follows. First, information is extracted out of the system artifacts. Second, this information is analyzed in order to take adequate modernization decisions and finally, the information must be transformed to new artifacts. These steps are supported by metamodels to describe existing systems, discoverers to automatically create models of these systems and, tools to understand and transform complex models created out of existing systems. The *Knowledge Discovery Metamodel (KDM)* and the *Abstract Syntax Tree Metamodel (ASTM)* are

two complementary and relevant ADM standards (KDM, 2011) (ASTM, 2011).

This chapter analyzes ADM-based software modernization. It provides an overview of the-state-of-the-art in software modernization techniques. Taxonomy of different techniques is described. A description of how traditional techniques such as static and dynamic analysis can be integrated with ADM standards is presented. We propose a framework for ADM software modernization that integrates different paradigms. Finally, challenges and strategic directions in software modernization are included.

BACKGROUND

25 years ago, modernization focused mainly on reverse engineering for recovering high-level architectures or diagrams from procedural code to face up with problems such as comprehending data structures or databases or the Y2K problem. At that time, many different kinds of static analysis techniques had been developed and several studies had been carried out to compare them.

Later years, new approaches were developed to identify objects into legacy code and translate this code into an object-oriented language. Object-oriented programs are essentially dynamic and present particular problems linked to polymorphism and late binding, abstract classes and dynamically typed languages. Then, the focus of object-oriented software analysis moved from static analysis to dynamic one, more precisely static analysis was complemented with dynamic one. Many works had contributed to reverse engineering object-oriented code. Muller, Jahnke, Smith, Storey, Tilley, and Wong (2000) present a roadmap for reverse engineering research for the first decade of the 2000s. Fanta and Rajlich (1998) describe the reengineering of a deteriorated object-oriented industrial program written in C++. Systa (2000) describes an experimental environment to reverse engineer JAVA software

integrating dynamic and static information. Demeyer, Ducasse, and Nierstrasz (2002) distinguish a variety of techniques for object-oriented reengineering based on patterns.

When the Unified Modeling Language (UML) (UML, 2015) emerged, a new problem was how to extract higher-level views of the system expressed by different kind of UML diagrams. The diagrams that could be reverse-engineered in this way were partial. A new challenge was how to identify different relationships (e.g. dependency, association, aggregation and composition). Although there is relevant work for extracting UML diagrams from source code, many challenges still need to be done. Tonella and Potrich (2005) provide a relevant overview of techniques that have been investigated and applied in the field of reverse engineering of object-oriented code. Authors describe the algorithms involved in the recovery of UML diagrams, such as class diagrams, state diagrams, and sequence diagrams from code. This proposal is based on static and dynamic analysis.

Other works are linked to MDD-based reverse engineering. MacDonald, Russell, and Atchison (2005) report on a project that assessed the feasibility of applying MDD to the evolution of a legacy system. Deissenboeck and Ratiu (2006) show the first steps towards the definition of a metamodel that unifies a conceptual view on programs with the classical structure-based reverse engineering metamodels. Reus, Geers and van Deursen (2006) describe a feasibility study in reengineering legacy systems based on grammars and metamodels. At that moment, Canfora, Di Penta and Cerulo (2011) present a relevant survey that compares existing work in the reverse engineering area, discuss success stories and main achievements, and provide a road map for possible future developments in this area. Fleurey, Breton, Baudry, Nicolas, and Jézéquel (2007) report on the use of MDE as an efficient, flexible and reliable approach for a software migration process. The described process, developed at Sodifrance, includes automatic analysis of the existing code, reverse engineering of abstract high-level models,

model transformation to target platform models and code generation. Sodifrance has developed a tool suite for model manipulation called Model-In-Action (MIA) used as a basis for automating the migration.

New works are related to ADM. Barbier, Deltombe, Parisy, and Youbi (2011) describe a model driven reverse engineering method based on metamodeling and model transformation. The method was implemented in the BLU AGE® Reverse module, an Eclipse IDE plugin. In this approach, a textual DSL is constructed to later describe source code as formal KDM models. Next, these KDM models are transformed to UML PIMs (BLUE AGE, 2016). Authors generalize this method by extending KDM along with an implementation of the ASTM standard. Authors state that the link between KDM and ASTM is not clear even confusing.

Many CASE tools support reverse engineering, however, they only use more basic notational features with a direct code representation and produce very large diagrams (CASE MDA, 2016). Few MDA-based CASE tools support any of the QVT languages. As an example, IBM Rational Software Architect and Spark System Enterprise Architect do not implement QVT. Other tools partially support QVT, for instance Together allows defining and modifying transformations Model-to-Model (M2M) and Model-to-Text (M2T) that are QVT-Operational compliant. Medini QVT partially implements QVT (Medini, 2015). It is integrated with Eclipse and allows the execution of transformations expressed in the QVT-Relation language.

Nowadays, the most complete technology that supports ADM is MoDisco, a Generative Modeling Technology (GMT) component for Model-Driven Reverse Engineering (MoDisco, 2016). As an Eclipse component, MoDisco can be integrated with plugins or technologies available in the Eclipse environment such as Eclipse Modeling Project (EMP), Eclipse Modeling Framework (EMF), and model-to-model transformation. The Model-to-Model Transformation (MMT) Eclipse

project is a subproject of the top-level EMP that provides a framework for model-to-model transformation languages. Transformations are executed by transformation engines that are plugged into the Eclipse Modeling Infrastructure. The main transformation engines developed in the scope of that project are ATL and QVT (ATL, 2016). To date, the QVT declarative component is in its “incubation” phase and provides only editing capabilities to support the QVT language.

SOFTWARE MODERNIZATION TECHNIQUES

This section describes modernization techniques based on traditional techniques and ADM. Besides, it analyzes the influence of formal methods in this area.

Static and Dynamic Analysis

Static analysis extracts static information that describes the software structure reflected in the software documentation (e.g., the source code text) whereas dynamic analysis information describes the structure of the run-behavior and can be extracted by using debuggers, event recorders and general tracer tools. Static analysis is based on classical compiler techniques and abstract interpretation (Tonella, & Potrich, 2005).

Data-flow graph and the generic flow propagation algorithms are specializations of classical flow analysis techniques. Because there are many possible executions, it is usually not reasonable to consider all state of the program. Thus, static analysis is based on abstract interpretation of program model state that is easier to manipulate, although it loses some information. These ideas, applied in compiler optimizations, require information about program semantics and are semantics-preserving program transformations.

Ernst (2003) provides a comparison of static and dynamic analysis from the point of view of their synergy and duality. He argues that static

analysis is conservative and sound. Conservatism means reporting weak properties that are guaranteed to be true, preserving soundness, but not strong enough to be useful. Soundness guarantees that static analysis provides an accurate description of the behavior, no matter on what input or in what execution environment. Dynamic analysis is precise given that it examines the actual run-time behavior of the program, however the results of executions may not generalize to other executions.

The combination of static and dynamic analysis can enrich reverse engineering process. There are different ways of combination, for instance performing first static analysis and then dynamic one or perhaps, iterating static and dynamic analysis.

ADM Techniques

ADM refers to the process of understanding and evolving existing software assets for software improvement, modifications, interoperability, refactoring, restructuring, reuse, porting and migration. Next, we describe the main ADM standards related to modernization.

Standards for Modernization: KDM and ASTM

The key motivation for the establishment of standards for the interchange of software models within the ADMTF context is to facilitate interoperability between the tools and services of the adherents of the standard (ADM, 2015).

KDM and ASTM are two complementary and relevant ADM standards. ASTM acts as the lowest level foundation for modeling of software within the OMG ecosystem of standards, whereas KDM serves as a gateway to the higher-level OMG models.

ASTM complements KDM by providing a continuous framework for mapping between low-level software models that are represented in ASTM and higher-level conceptual views of software that are represented by KDM and other OMG modeling standards such as UML (UML, 2015).

Knowledge Discovery Meta-Model (KDM)

The main goal of KDM is to provide a common interchange format that allows interoperability between tools for maintenance, evolution, assessment and modernization.

KDM is defined via MOF and determines the interchange format via the XMI (XMI, 2011). KDM is a metamodel for knowledge discovery in software that allows representing information related to existing software assets, their associations, and operational environments regardless of the implementation programming language and runtime platform. KDM represents entire enterprise software systems, not just code. KDM separates knowledge about existing systems into several orthogonal facets known as Architecture Views. The KDM specification is organized into the following 4 layers, each layer is further organized into packages which define a set of metamodel elements whose purpose is to represent a certain independent facet of knowledge related to existing software systems (KDM, 2011): Infrastructure Layer, Program Elements, Layer, Runtime Resource Layer and Abstractions Layer.

Abstract Syntax Tree Metamodel (ASTM)

In the MDD context, ASTs are used as a model of the source code. ADMTF has defined ASTM, a specification for modeling elements to express AST in a representation that facilitates the interchange of software models among tools (ASTM, 2011).

ASTM describes the elements used for composing AST models. An ASTM model is a model of how the statements of a software asset are structured reflecting the grammar of the particular programming language.

To provide uniformity as well as a universal framework for extension, the ASTM specification is composed of the Generic Abstract Syntax Tree Metamodel (GASTM), the Specialized Abstract

Syntax Tree Metamodels (SASTMs) and the Proprietary Abstract Syntax Tree Metamodels (PASTM).

Metamodel Formalization

Metamodeling is a central aspect to many modeling frameworks. Then, it is important to reason with formal specification about them. However, progress in this direction is still emerging.

Jackson, Levendovszky, and Balasubramanian (2011) state that there has been a general consensus that MOF is underformalized and attempts at full formalization of MOF or like-MOF metamodels have not yet enabled extensive automated reasoning on metamodeling frameworks. One reason may be the strong association of MOF with OCL. OCL has a denotational semantics that has been implemented in tools allowing dynamic validation of snapshots. However, it cannot be considered strictly a formal specification language due to a formal language must at least provide syntax, some semantics and an inference system. Willink (2011) states that OCL contains many inconsistencies and evolves with MDA standards.

Many approaches, based on different formal specifications, support limited automated reason (Jouault & Bezivin, 2006) (Boronat & Meseguer, 2010) (Anastasakis, Bordbar, Georg & Ray, 2007).

Jackson, Levendovszky, and Balasubramanian (2011) present a relevant approach to specify metamodeling frameworks modularly using algebraic data types and constraint logic programming (CLP). Proofs and test-case generation are encoded as CLP satisfiability problems and automatically solved by using their FORMULA framework. Hassam, Sadou, Le Gloahec & Fleuquin (2011) propose a tool to help the designer to make a decision on the constraints attached to a metamodel during its evolution. This approach consists in identifying the impact of a change made at metamodel level on its associated constraints.

Favre (2009) presents a special-purpose algebraic language called NEREUS to provide extra support for metamodeling. NEREUS takes

Figure 1. Software modernization

advantage of existing theoretical background on formal methods, for instance, the notions of refinement, implementation correctness, observable equivalences and behavioral equivalences that play an essential role in model-to-model transformations. Most of the MOF metamodel concepts can be mapped directly to NEREUS. NEREUS allows specifying metamodels such as the Ecore metamodel, the specific metamodel for defining models in EMF (EMF, 2016). The NEREUS semantics was given by translating it to CASL language (Bidoit & Mosses, 2004). An appropriate set of tools to make formal metamodeling feasible in practice is provided. It includes a parser for NEREUS language, a translator from NEREUS to CASL and application that provides the ability to write specification in NEREUS, integrating the analyzer and the translator. Favre and Duarte (2016) describe formal metamodeling in NEREUS and tool support.

A MODEL-DRIVEN MODERNIZATION FRAMEWORK

We describe a framework for software modernization that integrates traditional reengineering

techniques with MDA, ADM and formal specification. The framework identifies three layers linked to reverse engineering, refactoring and forward engineering (Figure 1).

The basic steps are organized as a series of model transformations. Before reverse engineering, it is necessary a previous step for injecting models from the software to be modernized. This transformation is a Text-to-Model (T2M) transformation. After this injection step, Model-to-Model (M2M) transformations (linked to reverse engineering and restructuring stages) are applied until obtain high-level views of the artifacts involved in the modernization process. Finally, in the forward engineering stage, Model-to-Text (M2T) transformations are applied to generate new applications.

The reverse engineering distinguishes three different abstraction levels linked to models, metamodels and formal specifications. These models provide a uniform representation of the system in the ADM standard context (Figure 2).

In the MDD context, the reverse engineering stage extracts elements from existing systems and represents them into a Platform Specific Model (PSM), and subsequently Platform Independent Models (PIMs) are obtained from the PSMs. In the ADM context, KDM is the support for rep-

Figure 2. Model driven reverse engineering

representing PSMs by using ASTM as intermediate representation of a software system. The models at PIM level are built from PSMs by means of transformation (formal mappings) between KDM and UML.

The model level includes code, PIMs, PSMs and ISMs (Implementation Specific Models). PIMs are expressed in UML and OCL and include use case diagrams, activity diagrams, interaction diagrams to model system processes and state diagrams to model lifecycle of the system entities. PSMs are expressed as KDM models. An ISM is a specification of the existing system that is expressed by means of the code and its abstract representation (AST).

At model level, transformations are based on classical compiler construction techniques. They involve processes with different degrees of auto-

mation which range from totally automatic static analysis to processes that require human intervention to dynamically analyze the resultant models. All the algorithms that deal with reverse engineering share an analysis framework. The basic idea is to describe source code or models by an abstract language and perform a propagation analysis in a data-flow graph called in this context Object-Data Flow Graph (ODFG) (Tonella & Potrich, 2005). The static analysis is complemented with dynamic analysis supported by tracer tools.

The metamodel level includes metamodels defined via Meta-Object Facility (MOF), such as UML, KDM and ASTM, which describe the transformations at model level. A metamodel is an explicit model of the constructs and rules needed to construct specific models. MOF metamodels use an object modeling framework that is essentially

a subset of UML. The modeling concepts are classes that model MOF metaobjects, associations that model binary relations between metaobjects, data types that model other data, and packages that modularize the models. The metamodel level includes the UML metamodel that describes families of PIMs, the KDM metamodel that describes families of PSMs and the ASTM metamodel that describes ASTM models. Metamodel transformations are specified as contracts between a source metamodel and a target metamodel. MOF metamodels “control” the consistency of these transformations.

The level of formal specification includes specifications of MOF metamodels and metamodel-based transformations in the metamodeling language NEREUS.

Refactoring is a change made to the internal structure of software to make it easier to understand and cheaper to modify without changing its observable behavior. The Refactoring stage is a sequence of particular M2M transformations in which the source and target models conform to the same metamodel.

The forward engineering stage is the process of moving from high-level abstractions expressed as MDA models into implementations through a sequence of M2M transformations according to MDA principles.

Different realizations of this framework reflect different scenarios of modernization. As a realization of this framework, we proposed a process to migrate Java or C++ applications to mobile platforms (Diaz Bilotto & Favre, 2016).

CHALLENGES ON ADM-BASED MODERNIZATION

The success of legacy system modernization depends on the existence of technical frameworks such as MDA and ADM to cope with the diversity of languages and technologies used to develop a single software system.

Today, the most complete technology that supports ADM is MoDisco. However, MoDisco only supports reverse engineering of class diagrams. Important research issues to be addressed within the context of MoDisco include reverse engineering of different diagrams and advanced composition of heterogeneous models, scalability of model manipulation techniques and traceability during the whole life cycle of a MDD project.

We can summarize benefits of MDD approach as follows. It increases productivity due to the automation introduced in the generation of artifacts. It is more profitable, if the number of migrations is large and there are many applications of the same type to be migrated.

The models play the role of decoupling element to ensure the independence of source and target models with respect to their underlying technologies. Independence is achieved with injectors, M2M and M2T transformations that generate models independent of the source model, and by means of M2M and M2T transformations that construct a target model from independent models. Besides, a modernization process can be extended adding or replacing existing stages. In a chain of transformations, the models provide a valid extension point to add new stages.

The limitations of MDE approach are related to its maturity degree. KDM offers a reduced level of detail and does not distinguish concepts common to many technologies. The debugging process for M2M transformations is limited. Another limitation is the lack of open-source injectors and/or metamodels for programming languages.

The lack of predefined solutions for reverse engineering is another challenge. Sometimes a series of problems such as refactoring, or pre-static analysis of code are relatively general and can be applied to a large number of migration projects. Therefore, it would be interesting to have predefined solutions that express them in terms of standard metamodels

Bruneliere, Cabot, Dupé and Madiot (2014) state that the MoDisco approach is used as a

solid base for real applications, however, some important improvements on model driven reverse engineering techniques are still needed. They affirm that important research issues to be addressed including scalability of model manipulation techniques, advanced composition of heterogeneous models and traceability during the whole life cycle of a project.

To use formal methods that place change and evolution of models and metamodels in the center of the software development process is another challenge. In particular, with the existing verification tools, simple changes in a system require to verify its complete specification again making the cost of the verification proportional to its size.

CONCLUSION

This chapter presents state of the art in the Model Driven Modernization area. Taxonomy of different modernization techniques is described. Particularly, we analyze traditional reverse engineering techniques based on lstatic analysis and dynamic analysis and ADM-based techniques.

Modernization of legacy systems is a new research area in the software industry intended to provide support for transforming an existing software system to a new one that satisfies new demands.

We show that technical frameworks for information integration and tool interoperability that allow managing new platform technologies, such as MDA and ADM, can help to achieve the goals of software modernization. Particularly, we propose a framework ADM compliant to reverse engineering models from object-oriented code based on the integration of static and dynamic analysis, metamodeling and formal specification. The framework distinguishes three different abstraction levels linked to models, metamodels and formal specifications.

We described challenges and open problems in Model Driven Software Modernization. We believe that the adoption of this approach can au-

tomatize crucial steps of a modernization process, reducing costs and development time.

KEY TERMS AND DEFINITIONS

ADM (Architecture Driven Modernization):

The process of understanding and evolving existing software assets of a system of interest in the context of MDA.

ATL (Atlas Transformation Language):

A model transformation language and toolkit developed on top of the Eclipse platform that provides ways to produce target models from source models.

MDA (Model Driven Architecture):

An initiative of OMG for the development of software systems based on the separation of business and application logic from underlying platform technologies. It is an evolving conceptual architecture to achieve cohesive model-driven technology specifications.

MoDisco:

A generic, extensible and global Model Driven Reverse Engineering approach and a framework implemented as an official Eclipse project on top of the Eclipse platform.

MOF (Meta-Object Facility): A meta-model that defines a common way for capturing the diversity of modeling standards and interchange constructs involved in MDA.

QVT (Query, View, Transformation): A meta-model for expressing transformation in MDA-based processes.

Reverse Engineering: The process of analyzing available software artifacts such as requirements, design, architectures and code, in order to extract information and provide high-level views of the system.

Mutation Testing Applied to Object-Oriented Languages

INTRODUCTION

Mutation testing is a suitable technique to determine the quality of test suites designed for a certain program. This testing technique is based on the creation of *mutants*, that is, versions of the original program with an intentionally introduced fault. Mutations are inserted within the code through some defined rules called *mutation operators*. The underlying idea is that a good set of test cases for the system under test (SUT) should be able to detect any changes generated affecting the behavior of the application.

Test cases are supposed to produce the correct output when they are run on the original program. When the output of a mutant is different from the output of the original program for a test case, the mutation has been revealed and the mutant is classified as *dead*. Otherwise, the mutant is still *alive* and needs to be executed against the rest of the test cases to detect its modification. Hence, if some mutants remain alive after the whole test suite execution, new test cases can be added in order to kill these surviving mutants. However, we classify a surviving mutant as equivalent when the meaning of the program has not actually been modified despite the injected mutation.

Mutation operators represent typical mistakes made when programming and they produce a simple syntactic change in the SUT. Mutation testing is a *white-box* testing technique, i.e., it tests

a program at the source code level. Therefore, the set of mutation operators and the overall technique should be developed around each programming language in particular; the correct choice of the set is one of the keys to successful mutation testing. Thus, we can find an assortment of research studies devoted to the definition of mutation operators for specific languages and tools automating the generation of mutants.

In the same sense, a set of mutation operators can be defined at different levels in each language. Mutation operators mainly dealing with variables, operators or constants were designed for some procedural programs in the early years of the technique. However, other mainstream languages as Java, C# or C++ also include object orientation and completely different mutation operators are needed to test the new structures in these languages. As an example, the operator *IHD* (Hiding Variable Deletion) deletes a variable member in a subclass which is hiding a variable in a parent class:

Original code:

```
class Base{      class Child: public
Base{
public:          public:
    ...          ...
    int v;       int v;
};              };
```

Mutated code:

DOI: 10.4018/978-1-5225-2255-3.ch649

```

class Base{      class Child: public
Base{
public:          public:
    ...          ...
    int v;       /*IHD*/
};              };

```

The purpose of the chapter is to look in depth at the development and the current state of mutation testing, and more specifically, with regard to object-oriented programming languages, in order to widely make known this technique in the computer science research field. Next sections deal with the related work, the steps to accomplish in the mutation testing process, the approaches to evaluate mutation operators and the existing techniques to improve the problems of this technique: equivalent mutant detection, test data generation and the expensive computational cost. Finally, the definition and evaluation of mutation operators for object-oriented languages will be focused.

BACKGROUND

Mutation testing was originally proposed by Hamlet (1977) and DeMillo, Lipton and Sayward (1978) and its development has taken place in parallel with the appearance of the different programming languages (Offutt & Untch, 2001). As a result, in the early years, most of the works centered on procedural programming languages: Agrawal et al. (1989) defined a set of 77 mutation operators for C, the tool *Mothra* was developed including 22 operators to apply mutation testing to Fortran (King & Offutt, 1991) and Offutt and Pan (1996) composed a set of 65 operators for the Ada language. The mutation operators for these procedural languages are known as *traditional* operators.

However, recently, new languages and paradigms have drawn the attention as well as the research has expanded towards other domains (Jia & Harman, 2011). As an illustration, we can find testing tools for rather different languages

like *SQLMutation* for SQL (Tuya, Suárez-Cabal & de la Riva, 2007), *Gamera* for WS-BPEL (Domínguez-Jiménez, Estero-Botaro, García-Domínguez & Medina-Bulo, 2009) or *AjMutator* for AspectJ (Delamare, Baudry & LeTraon, 2009). The existing mutation tools have been enumerated by Jia and Harman (2011). Finally, new mutation frameworks have been also developed lately: *Mutpy* (Derezińska & Halas, 2014) for Phyton 3.x, *Mutant* (n.d.) for Ruby or *PIT* (Van Laeden, 2012) for Java and other JVM languages.

The attention to the object-oriented (OO) paradigm has also risen and several papers and tools have appeared, mainly around Java (Ahmed, Zahoor & Younas, 2010). The first definition of class operators for Java was accomplished by Kim, Clark and McDermid (2000). As exposed in that paper, the aforementioned traditional operators can be applied to test OO programs, but those operators that were developed in programming environments away from this paradigm, do not take into account some types of faults related to features of this kind of programs, so operators at the class level are definitely necessary. Mutation tools including class mutation operators are *MuJava* (Ma, Offutt & Kwon, 2005) for Java, *CREAM* for C# (Derezińska & Szustek, 2009) and *MuCPP* for C++ (Delgado-Pérez, Medina-Bulo, Domínguez-Jiménez, García-Domínguez & Palomo-Lozano, 2015).

All these languages, even though sharing part of the syntax, need a particularized study to define their set of mutation operators and tools to generate the mutants. Mutation testing, usually performed on programs at the unit level, has also been applied at other levels in addition to the class level. Hence, Delamaro, Maldonado and Mathur (2001) studied the technique to be used for integration testing and Mateo, Usaola and Offutt (2012) even to test a complete system. Mutation testing has also been performed on technologies relating the SOA architecture (Bozkurt, Harman & Hassoun, 2013). Furthermore, apart from the code, mutation testing has been used in other domains like the specification of models, such as Finite

State Machines (Fabbri, Delamaro, Maldonado & Masiero, 1994).

As the technique was evolving and it was applied to real-world and bigger applications, it became clearer the barriers that this technique involves, which are discussed by Offutt and Untch (2001): the high computational cost and the time that the user needs to spend, for example, to determine the equivalent mutants. Around these problems have emerged new fields of study so that the technique gets a higher degree of maturation (Usaola & Mateo, 2010; Grun, Schuler & Zeller, 2009). Besides, apart from the mutation score, new calculations are being used to enhance the effectiveness of the technique (Estero-Botaro, Palomo-Lozano, Medina-Bulo, Domínguez-Jiménez & García-Domínguez, 2014).

MUTATION TESTING OVERVIEW

Mutation Testing Steps

The mutation testing process consists basically in three main steps: the analysis of the program, the generation of mutants and the execution of the test suite. Before performing these phases, the correctness of the SUT is checked by executing the test cases on the program. If one of the outputs is incorrect, the tester needs to fix the program until all test cases are successfully executed. Then, the tester can start the process described below:

- **Analysis:** In this first step, the aim is to determine where in the code each mutation

operator can be applied. In other words, the analysis allows us to know the mutants that can be created from the code.

- **Generation of Mutants:** Once the tester finds out that a fault can be introduced, a new program is produced containing that syntactic change, i.e., the mutant is in fact generated.
- **Execution of the Test Suite:** The created mutant can be run against the test suite now. After the execution, the mutant is classified as dead or alive depending on the output.

Afterwards, the mutation score is computed (previously analyzing the equivalence), indicating if some of the mutants are still alive. Then, the tester has to decide whether to create new test cases to try to increase the mutation score or the result passes an established threshold. If new test cases are included, the process has to be performed again and again until the tester is satisfied.

The commented overall process is shown in Figure 1. Moreover, the test suite can be reduced when analyzing the results. In this reduction, the test suite should be non-redundant (a test case is not useful if other test cases detect the same mutants) and adequate (every mutant is killed by at least one test case) (Mresa & Botacci, 1999).

Quality of Mutation Operators

Evaluating the used mutation operators to obtain a test suite with quality is an important issue in this process and several authors have dealt with this aspect. The *mutation score* is the most common

Equation 1. General calculation of mutation score

$$MS(S,C) = \frac{KM}{TM-EM} \times 100$$

MS: Mutation score

S: SUT

C: Test cases

KM: Killed mutants

TM: Total mutants

EM: Equivalent mutants

Figure 1. General mutation testing process

criterion as this score is calculated to determine the test suite effectiveness distinguishing the mutants (see Equation 1); when all the mutants are killed ($MS=100$), we obtain an adequate test suite for the applied operators.

Mresa and Botacci (1999) used the mutation score in each particular mutation operator, while some studies have considered other dimensions like the number and kind of mutants generated. As a matter of fact, it is preferable not to use operators that generate a large number of equivalent mutants or we have to take care of operators that produce a great amount of mutants as they can entail much computation.

Smith and Williams (2009) proposed to determine the quality of operators by relating the possible mutant states after the test suite execution:

killed by the initial test suite, killed by a new test case, killed by a new test case specifically defined to kill another mutant or not killed. Likewise, Derezińska (2006) exposed an idea of the effectiveness regarding the class mutation operators (specifically for C#) as well as of the test cases for an operator. Derezińska and Rudnik (2012) analyzed both traditional and class operators depending on their influence in the mutation score, and Moghadam and Babamir (2014) measured the mutation score in terms of object-oriented metrics reflecting the structural complexity of a program.

Finally, Estero-Botaro et al. (2014) presented a mathematical formula to measure the operator quality. In short, the quality metric Q_m favors not only those mutants killed by few tests (therefore, the mutation may be difficult to detect), but also

when those few tests kill few mutants (therefore, the tests killing the mutant may be difficult to design analyzing other mutants).

Problems of Mutation Testing

Two are the chief remaining barriers for the definitive practical usage of the technique in the industry: the great amount of computation and the manual time spent by the user. Hence, many studies have been undertaken providing different solutions for these problems in the last years. In the case of the computational expense, several techniques have appeared reducing both the execution cost and the number of mutants generated (Usaola & Mateo, 2010). Within the former, we can stand out the following choices:

- **Weak Mutation:** Comparing the internal state of the mutant and the SUT right after the mutated fragment (Girgis & Woodward, 1985).
- **Firm Mutation:** Less strict than weak mutation, comparing the intermediate state after the execution and the final output (Woodward & Halewood, 1988).
- **Runtime Optimizations:** Such as the *meta-mutant* technique encoding all the mutants in a single program (Untch, Offutt & Harrold, 1993), or specific compilers for faster executions.

Attending the reduction of mutants, we can find:

- **Mutant Sampling:** Only executing some of the available mutants randomly (Budd, 1980).
- **Selective Mutation:** Applying a subset of the defined mutation operators (Mresa & Bottaci, 1999).
- **Mutant Clustering:** Grouping the mutants according to the set of test cases that kill them and then selecting a small number of mutants for each cluster (Hussain, 2008).

- **Higher Order Mutation:** Where the mutant contains more than a single fault (Jia & Harman, 2009).
- **Evolutionary Mutation Testing:** Generating a selected subset of mutants through an evolutionary algorithm (Domínguez-Jiménez, Estero-Botaro, García-Domínguez & Medina-Bulo, 2011).

While the problem of the cost is practically overcome nowadays, the lack of automation is not resolved in spite of the advances. Firstly, the automatic generation of test cases needs to be enhanced so that their creation is not manual. *Constrained-based test data generation* (CBT) is one of the techniques developed, consisting in the creation of values that satisfies certain constraints (DeMillo & Offutt, 1991). Some of their problems were alleviated in the *dynamic domain reduction procedure* (DDR) (Offutt, Jin & Pan, 1999). More recently, new approaches have been exposed, as the promising study to create new test cases with the goal of killing mutants in object-oriented systems (Fraser & Zeller, 2012) or the application of *search based testing* to mutation testing (Papadakis & Malevris, 2013).

Secondly, the analysis of the still alive mutants after the test suite execution to determine those that are equivalent supposes another time consuming labor. This task remains undecided, but it has been tried to be reduced in several works. Baldwin and Sayward (1979) first suggested compiler optimization techniques. Other techniques tackling with this problem are the usage of a *co-evolutionary* algorithm to cut out equivalent mutants in the process through a fitness function (Adamopoulos, Harman & Hierons, 2004), or the analysis of changes in the code coverage (Schuler & Zeller, 2010). Recently, the study by Papadakis, Jia, Harman and Le Traon (2015) succeeded in reducing equivalent mutants by comparing the executables of the original programs and the mutants.

MUTATION TESTING AT THE CLASS LEVEL

Class Mutation Operators for Object-Oriented Programming Languages

As far as the authors know, class mutation operators have been defined for three object-oriented programming languages; Java, C# and C++. The first operators at this level were defined for Java by Kim et al. (2000) and completed by Ma, Kwon and Offutt (2002). Derezińska (2006) and later Delgado-Pérez et al. (2015) defined class operators for C# and C++ respectively based on Java operators, but also presented specific operators for those languages.

Mutation operators are usually gathered in groups because of their structural similarities. Regarding operators at the class level, these are the main categories:

- **Encapsulation or Information Hiding:** Checking the correct accessibility.
- **Inheritance:** Between classes, mainly in presence of overriding members.
- **Polymorphism and Dynamic Binding:** Testing the proper functioning of these properties.
- **Method Overloading:** Confirming the right method is being invoked.

A general list of operators for these categories is shown in Table 1. Most of these operators can be applied to these programming languages, with exceptions such as *AMC* or *IOR* for C# and *JSD*, *JSI* or *EOC* for C++. Moreover, many of these operators have been appropriately tailored to the specifics of each language, changing the scope of application or even the name and the meaning. The concrete differences in the operators among these languages have been commented by Derezińska (2006) in the case of C#, and by Delgado-Pérez et al. (2015) regarding C++.

Table 1. Common class mutation operators

Category	Operator	Description
Encapsulation	<i>AMC</i>	Access modifier change
Inheritance	<i>IHD</i>	Hiding variable deletion
	<i>IHI</i>	Hiding variable insertion
	<i>ISD</i>	<i>super</i> keyword deletion
	<i>ISI</i>	<i>super</i> keyword insertion
	<i>IOD</i>	Overriding method deletion
	<i>IOP</i>	Overriding method calling position change
	<i>IOR</i>	Overriding method rename
	<i>IPC</i>	Explicit call of a parent's constructor deletion
Polymorphism and dynamic binding	<i>PCD</i>	Type cast operator deletion
	<i>PCI</i>	Type cast operator insertion
	<i>PCC</i>	Type cast operator change
	<i>PMD</i>	Member variable declaration with parent class type
	<i>PPD</i>	Parameter variable declaration with child class type
	<i>PNC</i>	<i>new</i> method call with child class type
	<i>PRV</i>	Reference assignment with other compatible type
Method overloading	<i>OMD</i>	Overloading method deletion
	<i>OMR</i>	Overloading method contents replace
	<i>OAN</i>	Argument number change
	<i>OAO</i>	Argument order change
Miscellany	<i>JTD</i>	<i>this</i> keyword deletion
	<i>JTI</i>	<i>this</i> keyword insertion
	<i>JSD</i>	<i>static</i> modifier deletion
	<i>JSI</i>	<i>static</i> modifier insertion
	<i>JID</i>	Member variable initialization deletion
	<i>JDC</i>	Default constructor creation
	<i>EOA</i>	Reference assignment and content assignment replacement
	<i>EOC</i>	Reference comparison and content comparison replacement

Table 2. Mutation operators within the exception handling category

Category	Operator	Description
Exception handling	<i>EHC</i>	Exception handling change
	<i>EHR</i>	Exception handler removal
	<i>EXS</i>	Exception swallowing

Table 3. Specific class mutation operators

Category	Operator	Description
Java-specific	<i>EAM</i>	Accessor method change
	<i>EMM</i>	Modifier method change
C++-specific	<i>IMR</i>	Multiple inheritance replacement
	<i>PVI</i>	<i>virtual</i> modifier insertion
	<i>CDD</i>	Destructor method deletion
	<i>CCA</i>	Copy constructor and assignment operator overloading deletion
C#-specific	<i>PRM</i>	Property replacement with member field
	<i>OID</i>	Overriding indexer deletion
	<i>OPD</i>	Overriding property deletion
	<i>IOK</i>	Override keyword substitution
	<i>DEH</i>	Method delegated for event handling change
	<i>DMO</i>	Delegated method order change
	<i>DMC</i>	Delegated method change

A further group, exception handling, has also been considered as a class-level category (Kim et al., 2000) because exceptions are related with the object-oriented paradigm (see Table 2). As aforementioned, several mutation operators have also been specified for each of these languages, which are presented in Table 3. The Java-specific operators shown in that table are also applicable to C#; still, because of the *property* feature, *EAM* and *EMM* have a limited importance in that language.

Different evaluations about these operators have yielded two main conclusions. First, the mutants created with operators at the class-level are fewer than with traditional operators. Second, the equivalence problem is a more important issue using class operators than traditional ones.

The study by Ma, Kwon & Kim (2009) showed that there were almost twice as many traditional mutants as class mutants for the same classes. In those experiments class operators produced an equivalence percentage over 70%, unlike the 5-15% usually found with traditional operators. Nevertheless, this high equivalence percentage was not confirmed by later studies; in the experiments conducted by Segura, Hierons, Benavides & Ruiz-Cortés (2011), about 45% of the mutants were equivalent and Delgado-Pérez et al. (2015) obtained 37% of equivalence percentage in their study for C++.

FUTURE RESEARCH DIRECTIONS

In brief, mutation testing needs more research to resolve the main objections to the usage of the technique. Regarding the equivalence detection, the future research may address the redefinition or reimplementation of the mutation operators to try to avoid the creation of equivalent mutants. Moreover, in general terms, the currently most used programming languages need more support as well as the most promising languages for the future. In this way, mutation testing can be a real choice in the testing phase and start being widely accepted and having a practical approach.

In the case of class mutation operators, they have not been analyzed at the same extent as traditional operators in the literature, so new studies on the significance of these operators are needed. In addition, an individual evaluation of the operators could be accomplished to obtain a sufficient set of operators at this level.

CONCLUSION

Along this chapter, we have tackled the main topics related to mutation testing, giving details about studies focusing object orientation. The structures related to this paradigm require a tailored analysis and a set of mutation operators at the class level

were defined to that end. These class operators have been defined for three languages, where we can find both common and specific operators for each language.

Although the amount of generated mutants is lower using class operators than traditional ones, equivalence is even a greater problem. Still, important recent advances like the automatic generation of test cases to kill mutants (Fraser & Zeller, 2012) and the reduction of equivalent mutants (Papadakis et al., 2015) are bridging the gap between research and uptake in the industry.

KEY TERMS AND DEFINITIONS

Alive Mutant: The mutant that produces the same output as the original program for a certain test case.

Class Mutation Operator: Mutation operator that injects the mutation regarding structures related to the object-oriented paradigm.

Dead Mutant: The mutant that produces a different output from the original program for a certain test case.

Equivalent Mutant: The mutant whose introduced change does not modify the meaning of the original program.

Mutation Operator: Represents a typical mistake produced by a programmer and it is used to introduce a simple syntactic change in the code to generate a mutant.

Mutation Score: The calculation to measure the quality of a test suite detecting the introduced faults in the mutants. It is defined as the quotient between the number of dead mutants and the number of non-equivalent mutants.

Mutation Testing (or Mutation Analysis or Program Mutation): A technique used to evaluate the quality of a test suite in the detection of faults and create new test cases.

Object–Oriented Programming in Computer Science

INTRODUCTION

In computer science, a program is composed of a series of commands, which runs within a computer or an electronic circuit, producing information for users. Programming is a that can help programmers while writing a program. Computer programming is the process of writing an algorithm and, it is also the encoding of the algorithm into a notation that can produce and provide information to the users. It can be classified into two groups, that is, system programming and application programming. System programming is a sub branch of the general programming that is composed of low level instructions which are used to operate and handle computer hardware. Application programming is considered as the improved version of the computer programs which can perform specific tasks for the users. One of the application programming types is the object oriented programming (OOP) which is about how information is represented in human mind.

As a computer programming approach, OOP is useful such that it provides easy modeling in designing and developing real entities. This approach is intended to model the entities and, also, the relationships existing between them. OOP allows programmers to define the required classes

to create the objects and to apply modifications (manipulations) on them. It can also supply inheritance, polymorphism and encapsulation features to the developers. With these capabilities, the processed data can be isolated from other redundant applications. Because of its abilities that are readily available to the users, OOP is preferred much more than other available programming languages. The inherent properties of OOP, which do not exist in other application programming, can be stated as modularity, extensibility and reusability. This chapter provides a substantial survey of OOP in computer science.

In this chapter, we have highlighted a number of explanations and reviews that are generally accepted and are in common use in OOP. We explain the heart of this chapter OOP concept in section 1, Object Oriented Programming Features, making up the largest section. Main topic of OOP which are included Inheritance, Polymorphism, Abstraction and Encapsulation titles are explained with details in the subtitles of section 1. In section 2, you can find an example of OOP implementation in Java. There are many kinds of OOP languages in use but in this study, Java was given as a strong example to OOP language (Harel, Marron, & Weiss, 2010). The following section is Future Research Directions which include future works related OOP. The

chapter ends with Conclusion section that gives a brief information about this study.

BACKGROUND

Programming paradigm is a fundamental style of computer programming which classifies programming languages. Different programming paradigms were developed by considering the concepts and abstraction which are used to represent the elements of a program, and steps that compose a computation. Some of the programming languages are designed to support one paradigm and some of them support multiple paradigms. Before OOP languages, there are also some other paradigms such as classic programming, modular programming and structural programming (Bista, Bajracharya, & Dongol, 2015). These programming techniques were helped the programmers while solving their problems. Depending on improving technology, new structure of OOP has emerged so one of these paradigms is OOP which changed radically the programming paradigm continued until the day it appeared. Software methodology used before OOP referred to by the name of the procedural programming. This methodology was based on advancing codes in a particular direction and calling the common function that is used to reduce the workload. This methodology, used in the software world for a long time, has some difficulties. First of all, application of the procedural programming developed as a whole cannot be divided. So, each developer working on the application has to know almost every building of application. Due to its building as a whole, it is hard to make changes on the application. The reason of these difficulties is that procedural programming is an abstract that is not able to model the real world. The real world can be simulated by programmers thanks to OOP by using objects and classes. Object-oriented approach enables to divide a complex system into smaller parts and manageable modules which makes development process easier to grasp and share among members

of a developer team and easier to communicate to users who are needed to provide requirements and confirm how well the system meets the requirements throughout the process (Dennis, Wixom, & Tegarden, 2015). Thus, OOP enables modularity and abstraction with increased code understanding, maintenance and expansion. OOP is formed by the collection of objects which communicate with each other in order to perform tasks. This communication is based on messages in OOP, and objects are created from classes.

Class is a blueprint which is used to define objects describing the contents of the objects itself. It is a user-defined prototype for an object that defines a set of attributes and methods which characterize any object of the class. These attributes are data members or variables (static attributes), and methods are dynamic behaviors, also called member functions. Data members and member functions are called class members. Attributes, which are attached to the classes, store information about the object (Robson, 1981). Data member has a name and a type; it holds a value of that type. Member function receives parameters from the caller (if it's required), performs the tasks which are defined in the function body and returns result or void to the caller.

In most of the programming languages, class keyword is used to define a class. Class declaration must contain the name of the class which programmer declares. Basic class declaration looks like this:

```
Class NameOfClass {
...
}
```

The other term, object, helps users to understand the object oriented notion. Objects, also called instances of a class, are modeled on real world entities. All the instances of a class have similar properties. Basically, objects have 2 characteristics, state and behavior. State is a well-defined condition of an item which captures the relevant aspects of an object. Behavior is the observable

Figure 1. A cat object and its methods

effects of an operation or event. For example, a software object that modeled real world cat would have variables that indicated the cat's current state:

- Its breed is Cymric
- Its color is Yellow
- Its age is 3.

These variables are formally known as instance variables because they contain the state for a particular cat object, and in the object oriented terminology, a particular object is called an instance. In addition to its variables, the software cat would also have methods from real cat's behaviors: to meow, to wag the tail, play the ball etc. Figure 1 shows three different method of cat object.

A class may contain a variable that is shared by all instances of class. These variables are defined within a class. Programmer can create new objects which can inherit the number of characteristics from one of the existing objects. Objects can communicate with each other by passing message. A

message is a method call from sender object to a receiver object. Object responds to a message by executing one of its methods (Legdarg, 1996). Additional information, along with the called arguments, may accompany a method call. A message includes three components. These components are object identifier which indicates the message receiver, method name, and arguments which can be required for the execution of the method. In the example of cat.play (cp), cat is an object and the receiver of the message, play is the method, and cp is the argument of play.

The basic implementation of 'cat' example is given in program 2 of Implementation of OOP Design in Java Programming section and this example is illustrated in Figure 2 with detail which include a diagram of cat class, cat class to address issues regarding the states, methods, attributes, etc. used in OOP.

1. OBJECT ORIENTED PROGRAMMING FEATURES

OOP has many features that make it usable including the followings:

- Inheritance
- Polymorphism
- Abstraction
- Encapsulation

Figure 2. Illustration of cat object

1.1. Inheritance

This concept points code reuse without repeating or rewriting the code. It includes the creation of new classes from existing classes, and these new classes are called derived class or sub class. The existing class is called the base class or parent class or super class. The derived class reuses the base class members, moreover it can add and alter them. So programmers can avoid rewriting and testing of code that already exist. The goal of inheritance is to support refinement of classes into derived classes or subclasses. There are many advantages of using inheritance concept in programming language. Direct modeling of such hierarchies makes the conceptual structure of programs easier to comprehend, inheritance supports that common properties of classes factorized that is described once and reused when needed (Wirfs-Brock & Johnson, 1990). This results in modularity and makes complicated programs easier to comprehend and maintain, since description is avoided. Inheritance hierarchies support a technique where the most general classes containing common properties of different classes. These classes are designed and verified first, and then, specialized classes are developed by adding more details to existing classes (Thomsen, 1986).

Inheritance implements the “Is-A” relationship. In OOP, Is-A relationship means that one object

is type of another one. For example, student is a person, car is a vehicle etc.

A class inherits instance variable declarations as well as methods from its base class. By adding new instance variables and new methods, and by overriding base class methods, the derived class’s attributes may be redefined. A derived class cannot access the private members of its base class; otherwise this situation would be against the concept of encapsulation. A derived class has access to the public and protected members of its base class. They are both inheritable and visible to users.

There are different types of inheritance that depends on programming language. *i)* Single Inheritance: A derived class, which is inherited properties and behaviors from a single base class, is called single inheritance. *ii)* Multi-Level Inheritance: If a class is derived from another derived class, it is called multi-level inheritance. *iii)* Hierarchical Inheritance: If more than one class is derived from a base class, it is called hierarchical inheritance. *iv)* Hybrid Inheritance: It is a combine form of single and multiple inheritance. *v)* Multiple Inheritance: If a class is derived from more than one class, it is called multiple inheritance.

1.2. Polymorphism

Dictionary definition of polymorphism is the property of something having many forms. In com-

Figure 3. A real world example of inheritance

puter science, polymorphism refers to the ability of a programming language to describe objects in different ways based on their class or data type (Gamma, Helm, Johnson, & Vlissides, 1994). It can be allowed to talk to an object even if it is not known exactly what the object is. Thanks to the polymorphism, size of programming applications can be made smaller. In addition, understanding these applications is easier than those of others. If polymorphism does not exist, programmers have to check the objects one by one to determine which type and method are called according the object type. Polymorphism is activated in such situations that frees the designer from this inconvenience and allows flexibility. To better understand the concept of polymorphism, it is needed to comprehend the inheritance well. Polymorphism is tied closely to the concept of inheritance in OOP languages. There is a simple rule that is called as “is-a”, to know whether or not inheritance is the right design for user’s data. This rule states that every object of the subclass is an object of the superclass. To explain the relationship between inheritance and polymorphism, an example is given in Figure 3. The figure represents a transportation class with subclasses including corresponding modes (sea, road, air, rail) and vehicles. For example, all the road vehicles are a vehicle type. Thus, it makes sense for the road vehicle class to be a subclass of the vehicle class. Naturally, the opposite is not true since not every vehicle is a road vehicle. All cars and bikes are road vehicles, so they can be grouped as a subclass of road vehicle class. Race car and normal car that are not shown in the figure are indicated subclasses of car class as seen below example. The most general concept of inheritance can be explained in this way:

Common features of race car and normal car:

- They are road vehicles
- They have an engine.
- They are designed to carry persons.
- They consume the fuel.
- They need a driver.

There are common features of car and bike:

- They are road vehicle
- They are designed to carry persons.
- They need a driver.

There are common features of road vehicle and sea vehicle:

- They are designed to carry persons.
- They need a driver.

As seen in the example, information just like “to carry persons” and “to need a driver” are repeated more than one. Each category of information does not need to be saved in these classes, because inheritance provides it directly. If common features are defined in vehicle class, all subclasses can take that information from only one class. By this way, if it is necessary to update the system, only one change related to the concept in vehicle class can be enough. And this is called polymorphism.

Polymorphism is also related to “overloading” and “overriding”. Overloading is a compile time polymorphism method that has the same name with different parameters. Overloading is a feature that enables a class to possess two or more methods having same name. Unless return type of method is same, error will occur.

Overriding is a run time polymorphism method that the implementation given in the base class is replaced with that in subclass. Override method can be added by rewrite the method that inherited from the base class. In this way, it provides the use of inherited class method. In this case, the software allows the flexibility that can make a different job by using the same method.

1.3. Abstraction

The word abstract means dissociated from any specific instance. Abstraction is to develop models in terms of interface and functionality instead of

implementation details. So it is related to encapsulation and data hiding (Yourdon, Whitehead, Thomann, & Oppel, 1995). Abstraction is applied to the model by considering the process of identifying object. It is used to reduce complexity of the design and implementation that focuses on the meaning of behaviors to avoid specification. Thanks to the abstraction, class internals are protected from user-level errors which breaks state of the objects (Wegner, 1987).

Abstract class is a parent class, which allows inheritance, containing abstract members. These members are only declared, not implemented. Implementation of abstract members is done within the derived class. Another type of a member is virtual member. Unlike abstract member, virtual members are implemented in parent class. To declare an abstract class, abstract keyword is used. Abstract member functions and properties are also declared with this keyword.

1.4. Encapsulation

From the user's point of view, a number of features are packaged in a capsule to form an entity. This entity offers a number of services in the form of interfaces by hiding the implementation details (Canning, Cook, Hill, & Olthoff, 1989). The encapsulation term is used to describe the hiding of the implementation details. The advantages of encapsulation are information hiding and implementation independence. Local variables are hidden in functions and private members are hidden in classes. Therefore, external direct access is prevented. If user does not know the implementation details, it is called information hiding. If user's interface is not affected by changing the implementation mechanics, it is called implementation independence (Booch, Maksimchuk, Young, Conallen & Houston, 2007). Class encapsulates the static attributes and the dynamic behaviors into the limited area to isolate and reuse when necessary. These operations cannot be done in the traditional programming languages. Private access control modifier hides data member of a

class from outside world. Access to these private data members is provided via public accessor functions. Objects do not have permission to know the implementation details of others. The implementation details are hidden within the class.

2. OOP DESIGN

People tell the daily concept with using spoken language. Programmers try to express the concept and the entity that is related to the problem, to computer with using programming languages. To do this, during the design phase, models providing an expression are created. Object-oriented method provides the creation of these models and (if necessary) updating the system.

In section 2.1 we have developed an object-oriented design for our cat system and in section 2.2 we implemented our object-oriented design in Java and showed how to convert class diagrams to Java code.

2.1. OOP Design with the UML Diagrams

Unified Modeling Language (UML) diagrams are used to describe the structure of systems. It is a standard for modeling object-oriented systems which defines sets of rules and vocabulary for conceptual and physical representation of system (Mallick & Das, 2013). It includes graphical notation to create visual model of the system (Booch, Rumbaugh, & Jacobson, 2005) which has well-defined semantics. UML in development process is used for object-oriented analysis and design. There are different diagramming techniques which is used to model a system. These diagrams can be grouped into 2 which are called structure and behavior diagrams. Structure diagram shows the static relationships and represents the data in a system which includes class, object, package, deployment, component, composite structure and profile diagrams. Behavior diagram shows the dynamic relationships between the instances or ob-

Figure 4. Class diagram modeling generalization of superclass Pet and subclasses Cat and Dog

jects. It includes use-case, sequence, statechart and activity diagrams. First of these diagrams called use case diagram is used to capture the requirements of the system and shows the relationships between the system and environment. Sequence diagram is a form of interaction diagram which is used to model the behavior of objects by focusing on time-based ordering of an activity. Statechart diagram shows the behavior of the classes. Activity diagram illustrates the flow of activities in a use case (Booch, Rumbaugh, & Jacobson, 2005).

It has developed an object-oriented design with UML class diagram for pets as shown in Figure 4.

Figure 4 is the class diagram that models generalization of superclass Pet and subclasses Cat and Dog. The following section 2.2, it is implemented our object-oriented design in Java and showed how to convert class diagrams to Java code (Deitel & Deitel, 2012).

2.2. Implementation of OOP Design in Java Programming

A university system can be given as an example, and this system is implemented by java programming language. The Java source code for the Person class is shown in Listing 1.

In this example, there is a base class which is called Person. This class includes basic informa-

tion, which people have, and there are 3 derived classes which inherit data and functions from the base class. These derived classes have their own methods and data members, and also they have methods and data members of Person class.

Keyword public is an accessibility modifier which refers the calling members or methods from external locations like other classes (Lea, 1999). AcademicPersonnel, administrativePersonnel and student classes call methods from Person class. Derived class methods are declared public because, they should be accessed from Main() method which Test class has. AcademicPersonnel class has a method called checkAcademicPersonnel(), this method is declared private. Private access specifier refers hiding data members and methods from other classes. Every class can access its own private data members and methods. If we try to reach this private checkAcademicPersonnel() method from Test class, it is going to fail. deliverCourse() method, which is declared public, can reach this private method because, they are in the same class.

Last class is called Test, which is developed to test other classes, it only has one method called Main. We create 3 different objects from 3 different derived class. Object academicPersonnel1 is created from academicPersonnel class which has deliverCourse() method on its own scope but, this

Listing 1.

```

1. public class Person
2. {
3.     public void printPersonalInformation(String id, String fName, String lName)
4.     {
5.         System.out.println(id+" "+fName+" "+lName);
6.     }
7. }
8. class academicPersonnel extends Person
9. {
10.     private boolean checkAcademicPersonnel()
11.     {
12.         return true;
13.     }
14.     public void deliverCourse(String courseCode, String courseName)
15.     {
16.         if(checkAcademicPersonnel())
17.         {
18.             System.out.println("Academic Personnel");
19.             System.out.println("Course: "+courseCode+ " "+ courseName);
20.         }
21.     }
22. }
23. class student extends Person
24. {
25.     void takeCourse(String courseCode, String courseName)
26.     {
27.         System.out.println("Course: "+courseCode+" "+courseName
28.     }
29. }
30.
31. class administrativePersonnel extends Person
32. {
33.     boolean checkStudentInformation()
34.     {
35.         return true;
36.     }
37. }
38. class Test
39. {
40.     public static void main(String[] args)
41.     {
42.         academicPersonnel academicPersonnel1 = new academicPersonnel();

```

continued on following page

Listing 1. Continued

```

43. student student1 = new student();
44. administrativePersonnel administrativePersonnell = new administrativeP-
ersonnel();
45. academicPersonnell.printPersonalInformation(("100305044", "Rahime", "Yilm
az"));
46. academicPersonnell.deliverCourse("CENG101", "Algorithms and Programming
I");
47. student1.printPersonalInformation(("214700560", "Anil", "Sezgin"));
48. student1.takeCourse("CENG102", "Algorithms and Programming II");
49. administrativePersonnell.checkStudentInformation();
50. }
51. }

```

object can also reach printPersonalInformation() method on Person class. Object student1 is created from student class, which has takeCourse() method on its own scope, and same as academicPersonnel class, student class is derived from Person class, so this object can reach base class methods. Third object is created from administrativePersonnel class which is derived from same base class.

For another example of the Java source code for the pet class is shown in Listing 2.

This example shows using abstract class. Abstract class is used to create a base template for derived classes. Pet class is the abstract base class which includes an abstract method called wag(). This method has no implementation, therefore it is declared abstract. There are two classes called dog and cat which are derived from pet class. These two derived classes provide an override method by using override keyword. Cat and Dog classes override wag() method, dog1.wag() invokes the wag() method declared in dog class, cat1.wag() invokes the wag() method declared in cat class.

FUTURE RESEARCH DIRECTIONS

To create (write) a program in any languages needs detailed training. That means a programmer have to be trained highly in the programming language that programmers wants to use. In the real life,

even if any person do not know any languages, they could write a computer program. Namely, untrained people can also create the program without using any programming languages. We can ask how it can be done. Instead of teaching a programming languages to a person, we can teach how to draw flow charts. When a correct flow chart is drawn, a case at the background of the flow chart can create a program source code by using the flow chart. If these kinds of cases can be created, an untrained person can write his program by using flow chart and produce his programming code. First of this, the basic flow chart symbols are taught and combination of this basic elements are told to the training people who wants to implement their problem by using flow chart. And then, it is expected to solve their problem. This solves the dependency of a programming language problem to implement a computer software.

CONCLUSION

The programming languages before OOP concept were not easy and friendly. Large and complex problems were solved by dividing into small systems. The real world modeling was not implemented by procedural programming. Creation of the real simulation of problems can be implemented

Listing 2.

26.   cat cat1 = new cat();
27.   dog1.wag();
28.   cat1.wag();
29. }
30. }

```

by the OOP. The functional programming shows more tendency for losing data while running according to OOP. The system requirements of data structure and data are more flexible in OOP than those in other models. The modification of all systems is more complicated than the object oriented system, since OOP system has a modular structure. All processes are done by using functions in former languages but in OOP, everything is processed by using objects methods.

The data is transferred by using messages among objects. By this way, objects can communicate among themselves. Data hiding properties of OOP attempt to protect the data from the outside modification request.

As a conclusion, the features of OOP, such as encapsulation, abstraction, polymorphism and inheritance help us to model the real life entities on computers. A more qualified and effective software can be created by using OOP.

KEY TERMS AND DEFINITIONS

Class: Used to define the objects and to describe the contents of the objects.

Java: A high level programming language that is based on object oriented design which was first released by Sun Microsystems in 1995.

Message: Communication type among methods.

Method: Called a function or a procedure that is used to operate on the data.

Object: Instance occurrence of a same class that models real-world items.

Object Oriented: A technique for programming that is based on the objects and on the relationship between those objects.

Programming: A mathematical methodology that helps programmers while writing a program.

The Past, Present, and Future of UML

S**Rebecca Platt***Murdoch University, Australia***Nik Thompson***Curtin University, Australia*

INTRODUCTION

Since its inception, the Unified Modeling Language (UML) has risen to relative ubiquity in the IT community. However, despite its status as an ISO industry standard (International Organization for Standardization, 2005), the UML is still evolving to accommodate the changing needs of industry. This development aims to ensure that UML remains effective and relevant to the most current developments in software engineering techniques. This article charts the progress of this arguably indispensable standard and discusses the ongoing evolution in three sections: The Past, The Present, and The Future. The Past section will detail the reasons for which standardization was needed, the history behind its inception and development, initial reception from the user community and also its initial effectiveness. The Present section then describes the various changes between UML 1.0 and UML 2.5. The reasons behind these changes and the effectiveness of them are then discussed. Finally in The Future section, the article will describe the current state of UML, predictions for the next specification of UML based on the Object Management Group documentation, and also common problems and suggestions from the wider community which may be addressed in future iterations of the specification.

BACKGROUND

The Unified Modeling Language is a form of notation that was developed with the core goal of

creating a standardized representation of general-purpose models, with the focus of functionality of these primarily being for software engineering and systems development. Despite this main focus of approach in the specification design, the language is meant to attain some level of applicability regardless of the subject matter. The reason a modeling language was needed in order to achieve this was to manage the complexity of the subject at hand - whether it was system or software design or another subject entirely. As a model is by nature an abstraction of reality, it allows the user to characterize the design of the subject in an effective manner. This abstract model then enables the user to better evaluate the subject and communicate that in an efficient and meaningful way rather than attempting to demonstrate their intentions using the actual software or system in question. In order to achieve this intended core goal the language has been modified and refined over time, resulting in evolutions of varying effectiveness and popularity.

THE EVOLUTION OF UML

The Past

In the late 1950s, the first object orientated programming language, Simula was introduced, and with it came “a powerful new combination of ideas into structuring computer programs, including instantiation of abstract data types, inheritance, and polymorphism” (Cook, 2012, p. 471). To accompany this new idea of object orientated

DOI: 10.4018/978-1-5225-2255-3.ch651

languages, methods for designing software in this object orientated way also started to emerge, and in time they were referred to as modeling languages. By the late 1980s there were more than fifty separate modeling languages - each with their own syntax, structure and notation. There were many issues with this overwhelming variety of languages and it has been noted that “such open-ended approaches [could] affect and constrain the system in unexpected ways or even result in failure. For example, system development and implementation failure rates remained stubbornly high. Cost overruns and time overruns were still the norm, rather than the exception” (Erickson & Siau, 2013, p. 296). As it was humanly impossible in this kind of environment for all system analysts and other relevant personnel to be trained in all methods, the lack of communication and technical understanding coupled with the fact that the majority of the languages available were unable to meet the demands required of them, led to alarmingly high project failure rates.

This lack of standardization and communication was not only negatively affecting development projects but also limiting the potential of object-orientated technology in general. In response to this very significant concern, The Object Management Group (OMG) was founded in 1989. The initial and presiding goal of OMG was to “create a standard for communication amongst distributed objects” (Cook, 2012, p. 472). This goal was intended to foster progress toward a common object model that would work on all platforms on all kinds of development projects. In order to further this goal specifically in the domain of modeling languages, OMG launched the Object Analysis and Design Special Interest Group to study design methods. This is also the origin point from which any Request For Proposals were issued.

Around the time that OMG was founded, a separate company called Rational was also attempting to implement a solution to the over saturation of modeling languages in use. To this end they recruited Grady Booch and James Rumbaugh in 1996. These men were the creators of

two of the dominant modeling languages of the time. Booch’s method was called Object-Oriented Design (OOD) (Booch, 1991) and Rumbaugh’s method was known as the Object-Modeling Technique (OMT) (Rumbaugh, Blaha, Lorensen, Eddy, & Premerlani, 1990). They were soon joined by Ivar Jacobson, whose Object-Oriented Software Engineering (OOSE) method (Jacobson, 1992) was also a prominent modeling language at the time. “The Three Amigos” as they later came to be known then set to work on the development of the Unified Modeling Language. A potentially universal standard form of notation with the intent to create ease of communication and reduce the risk of failure for projects, with human factors considered above all as this had been identified as a main failure point of previous projects (Erickson & Siau, 2013).

The UML 0.91 specification was the initial result of the unification of OOD, OMT, and OOSE, a somewhat successful endeavor as each base modeling language had unique strengths; Booch’s OOD was good for low level design, Rumbaugh’s OMT was effective for OO analysis, and Jacobson’s OOSE was good for high level design, as well as allowing for the implementation of use cases. Working with “The Three Amigos” were the UML Partners; a software development team who represented a range of different vendors and system integrators, who would collaborate to propose UML as the standard modeling language for the OMG (Kobryn, 1999). Representatives from other companies (such as IBM, Microsoft and Oracle) were consulted during the Object-Oriented Programming, Systems, Languages and Applications (OOPSLA) conference held that year, with the outcome of these consultations resulting in the UML 1.0 draft which was then submitted to OMG in response to the Request For Proposal. UML 1.0 was accepted by OMG in November, 1997.

The initial response after the release of the specification indicated that the Unified Modeling Language was very effective, once the personnel involved had made it past the difficult learning

curve of training in a new modeling language. In fact there is speculation that the response towards UML was actually too great - for while it was proven to be much more effective than its predecessors, it still had issues. The rapid uptake and positive response meant that the uptake of UML ended up growing at an alarming rate before it had finished standardizing properly.

The Present

When initially accepted as a standard, UML 1.0 appeared to meet all stated requirements and to be an effective modeling language. Since then, however, a number of revisions have taken place to alter the notation in order to fix various shortcomings and to become more effective. For example, some of the issues that were resolved between UML 1.1 and UML 1.3 included the lack of integration between certain model types, the absence of certain modelers and that some of the standard elements were named and organized inconsistently. There was also trouble with the architectural alignment – According to OMG “The submitters fell short of their goal of implementing a 4-layer metamodel architecture using a strict metamodeling approach. Instead they settled for the pragmatic, but less rigorous, loose (non-strict) metamodeling approach. This “adversely affected the integration of UML with other OMG modeling standards, such as the Meta Object Facility (MOF)” (Kobryn, 1999, p. 31).

As it is, The Object Management Group oversees standardization and it is through their processes that revisions of the UML are implemented. There are two mechanisms for standard revisions; RFPs and RTFs. The Request For Proposal (RFP) is the primary mechanism for updating specifications, while Revision Task Forces (RTF) are secondary. When a proposal is received, it is the RTF that examines and votes on the validity of it. The RTF is also able to recommend changes to the proposal in order to clarify areas that may be ambiguous. If the proposal is approved, then it becomes OMG adopted technology. If the proposal

is not approved, then the RFP is reissued, with changes made to it to reflect the reasons for the last proposal failing.

Through the OMG system, a number of significant changes have been made in response to some of the shortcomings identified in UML. Between UML 1.1 and UML 1.2, the specification was reformatted in order to better align with other OMG specifications. Typographical and grammatical errors were also targeted in this revision. Between UML 1.2 and UML 1.3, problems that had occurred during the alterations of the last revision were fixed, the activity graph notation was completed, and the standard elements were more formally organized. The revisions of the specification were all rather minor after that, up until UML 2.0 was released in 2005. The following UML Specification to be released was UML 2.4.1, and unlike UML 1.x this specification is organized into four sections. These sections are called the Superstructure, the Infrastructure, the Object Constraint Language, and the UML Diagram Interchange. The Infrastructure “defines the foundational language constructs required” (OMG, 2011, p. 1). This is then balanced by the UML Superstructure, which “defines the user level constructs required” (OMG, 2011, p.1). The current UML Specification in use is UML 2.5, which was released in June 2015. This version has been re-written to simplify the contents, increasing readability of the document. Other major changes include the removal of Infrastructure as a separate section of the Specification, and also “the compliance levels L0, L1, L2, and L3 have been eliminated, because they were not found to be useful in practise” (OMG, 2015a, p.11).

Studies have shown that the ongoing revision implementation has been successfully achieving the goal of standardization. As UML becomes more refined, it also becomes more universally accessible and accepted. A study found that 21% of Australian Computing Society members used UML frequently (Davies, Green, Rosemann, Indulska, & Gallo, 2006), further evidence of this growing standardization was demonstrated by

Dobing and Parsons (2006) who noted that class diagrams were the most frequently utilized aspect of UML as reported by 73% of participants. Since these studies were conducted it has been demonstrated that practitioners have been successfully implementing the Unified Modeling Language more effectively and frequently, to such a point that it is now a part of many undergraduate university curricula in Information Technology fields. More recent studies have shown that the growth and uptake of UML has persisted over time (e.g. Dobing & Parsons, 2010; Budgen, Burn, Brereton, Kitchenham, & Pretorius, 2011).

The Future

The next specification for UML, UML 2.6, currently has no known set or speculated release date. As it is too early in the development process for even the unofficial release specifications to be revealed to the general public, very little is known about this future specification update.

Based on comments regarding UML 2.6, it appears that the next version will cover minor revisions to the 2.5 specification, including fixing two sets of syntactical errors currently shown in the UML 2.5 metamodel. This expectation of only minor revisions is further supported by the list of issues shown to be resolved by the UML 2.6 Revision Task Force, which includes such changes as “Clarification of use case semantics” and “Parameterization of lifelines”, “such that Interactions can be used in slightly different context” (OMG, 2015b).

Issues, Controversies, Problems

Despite years of revision that have successfully yielded incremental improvements to the specification, problems remain that need to be addressed. The standard elements are still rather “bloated” and they contain a level of inconsistency in both naming and organization. This level of complexity and the inconsistencies introduced during revisions have been detrimental to the overall

readability of the specification. There is a concern that the design of the notation is not sufficiently user-friendly, which would discourage potential users from adopting and using UML in favour of other simpler alternatives such as DOT graph description language, as described by Erickson and Siau (2013).

Another potential issue that needs to be addressed concerns the cyclic nature of specification revisions. In the process of updating UML to attempt to deal with the above issues and problems, excessive addition, removal and alteration of major concepts could affect the core structure of UML. The current method of revision leaves the core structure vulnerable. As previously stated, the UML focus of functionality was primarily for software engineering. As a result, software tools offer extensive support for UML when used with this focus in mind. However there is very little support in software tools for any other application, despite the language’s goal of being a standardized representation of general-purpose models.

Solutions and Recommendations

The issue of “bloating” regarding the elements of UML is due to the inconsistent naming and organization within the standards. By phasing in more consistency to the various aspects of future specifications of the language, the volume of elements would be reduced and bloating would cease to be an issue. Reduction of elements and increase in consistency would also aid the uptake of the language among new users. Simplifying the language (and the specification documentation in relation to this) would increase the readability of it, and encourage more users to utilize UML instead of another modeling language. Also, core structure vulnerability can be corrected by the introduction of protocols within the specification revision procedure, to ensure that this remains unaltered. Support for non-software engineering projects is difficult to implement currently due to the fact that UML implementation seems to be “tool-based.” If all of the various tools used for

UML that are widely recognized started creating more support for the language in terms other than software engineering, then the specification would broaden to include this more as a result.

FUTURE RESEARCH DIRECTIONS

It has been shown that UML has been implemented within the field of software engineering increasingly over the years, moving from relatively low industry usage (e.g. Davies et al, 2006) to the present state where the growth in UML usage has led to an abundance of tools and software to better support the language. However, research into the Unified Modeling Language has been limited in recent years. There have been a few surveys conducted based on the use of UML in terms of software engineering and development, but very little in terms of its other applications as a general purpose modeling language. Current study seems to focus on the compliance of tools to UML, rather than the compliance of UML to its intended purpose. Future surveys of the adoption of UML (both within and outside of the field of software engineering) would be well served to include elements concerning the perceived effectiveness of the modeling language by users in real world situations. Another possible research direction may examine how the modeling language has affected development practices and utilization of techniques, and whether the overall project success rate has increased as a result of this.

CONCLUSION

The Unified Modeling Language may be the current industry standard, but it is still evolving and transitioning through constant revisions of the specification. These stages of revision are implemented to ensure that the UML remain effective and viable in the demanding and rapidly changing landscape of software engineering. This article

examined this evolution in terms of three main periods described as The Past, The Present, and The Future. The Past section detailed the reason behind which standardization was needed, the history leading up to and including the development of UML. The initial reception from the user community and initial effectiveness were also discussed. The Present section then described the various changes between UML 1.0 and UML 2.5 and the reasons behind these changes and their ongoing effects. Finally, The Future section described the current state of UML, the expectations for the next specification of UML and also some open issues from the wider community which are yet to be addressed. Some possible solutions and future research directions were also presented in light of these issues. In conclusion the Unified Modeling Language has proven itself to be an effective standard for communication and it will maintain its significant foothold in software engineering for the foreseeable future. However, the requirement for continual revisions to the specifications will also remain as the expected functionality and needs of UML practitioners will continue to change over time.

KEY TERMS AND DEFINITIONS

Model: A conceptual diagram used to represent a system.

Object Management Group: An organization created with the goal to determine a standard method of communication between distributed objects.

OOPSLA: “Object-Oriented Programming, Systems, Languages and Applications” – an annual research conference run by the Association for Computing Machinery.

Software Engineering: The application of systematic methods and approaches for the development and maintenance of software artifacts.

Specification: The set of requirements that must be satisfied in order for any model to comply with the current standards of UML.

Unified Modeling Language: A form of notation developed with the core goal of creating a standardized representation of general-purpose models, with the focus of functionality primarily being for software engineering.

Petri Nets Identification Techniques for Automated Modelling of Discrete Event Processes

Edelma Rodriguez-Perez

CINVESTAV Unidad Guadalajara, Mexico

Ernesto Lopez-Mellado

CINVESTAV Unidad Guadalajara, Mexico

INTRODUCTION

Building Petri net models from system behaviour observations is a hard task when the system is large and complex; then, the use of computer-aided modelling tools is useful. Identification techniques have been useful for building systematically models involving events and states. Finite automata and Petri nets have been used as a formalism to describe the functioning of discrete event processes in operation.

Reactive systems are embedded within an environment interacting with other systems. We focus on systems that interact through binary sig-

nals, which is the case of discrete event processes. The behaviour of the system is then captured as sequences of vectors whose entries are the values of input-output signals; afterwards, the sequences are processed by an identification method to obtain the discrete event model. This is shown in Figure 1.

This chapter surveys relevant identification methods and overviews two approaches that generate models of different levels of abstraction; one that describes in detail the relationship between input events and outputs, and other that yields compact descriptions. Finally, current research problems and trends on discrete event process identification are discussed.

Figure 1.

BACKGROUND

1. Identification Methods

1.1. Language Learning Methods

Pioneer works on identification methods can be found in computer science theory, where the problem of obtaining a language representation from sets of accepted words has been dealt since a long time. Such methods are generally referred as *language learning techniques*.

Gold's method (Gold, 1967) for identification in the limit processes positive samples: an infinite sequence of examples such that the sequences contain all and only all the strings in the language to learn.

The Probably Approximately Correct (PAC) learning technique in (Valiant, 1984) learns from random examples and studies the effect of noise on learning from queries.

The query learning model proposed in (Angluin, 1988) considers a learning protocol based on a "minimally adequate teacher"; this teacher can answer two types of queries: membership query and equivalence query.

Several works adopted state machines as representation model, allowing describing the observed behaviour.

In (Booth, 1967) a method to model a language as Moore or Mealy machines is presented. The method proposed in (Kella, 1971) allows obtaining models representing Mealy machines from a single observed input-output sequence. In (Biermann & Feldman, 1972) a method to identify non deterministic Moore machines based on a set of input-output sequences is presented. The method presented in (Veelenturf, 1978) processes simultaneously a sample of sequences to produce stepwise convergent series of Mealy machines, such that the behaviour of every new machine includes the behaviour of the previous one. Later, in (Veelenturf, 1981) an algorithm to identify a unique Moore machine generating the behaviour observed during m sequences starting at the same

initial state is proposed. This method is improved in (Richetin, Naranjo & Runeau, 1984); it proposes two algorithms to identify multiple systems.

Other works use as description formalism Petri net models. In (Hiraishi, 1992) an algorithm for synthesising Petri net models is presented. The proposed algorithm has two phases. In the first phase, the language of the target system is identified in the form of DFA. In the second phase, the algorithm guesses from the DFA the structure of a Petri net that accepts the obtained language.

1.2. Methods for Process Identification

In recent years, identification approaches (based on Petri net or automata) have been proposed for obtaining approximated models of Discrete event process whose behaviour is unknown or ill-known. In the context of manufacturing processes, identification methods can be complementary to established modelling techniques.

The incremental synthesis approach, proposed in (Meda, Ramirez & Lopez, 2000), (Meda & Lopez, 2001), (Meda & Lopez, 2003), deals with unknown partially measurable concurrent discrete event systems (DES) exhibiting cyclic behaviour. Several algorithms have been proposed allowing the on-line building of interpreted Petri net (IPN) models from the DES outputs. Although the techniques are efficient, the obtained models may represent more sequences than those observed.

In (Giua & Seatzu, 2005) a method to build a free labelled PN from a finite set of transitions strings is presented. This method is based on the resolution of an Integer Linear Programming (ILP) problem; the obtained PN generates exactly the observed language. Both the ILP statement and its solution are computationally demanding. This approach has been extended to other PN classes (Cabasino, Giua, & Seatzu, 2007; Dotoli, Fanti, & Mangini, 2008; Fanti & Seatzu, 2008; Dotoli et al., 2011); however, issues regarding applications to actual industrial DES have not yet been addressed in these works.

Another recent off-line method (Klein, Litz, & Lesage, 2005) allows building a non-deterministic finite automaton (FA) from a set of input/output (I/O) sequences, experimentally measured from the DES to be identified. Under several hypotheses, the constructed FA generates exactly the same I/O sequences of given length than observed ones. The method was conceived for fault detection in a model-based approach (Roth, Lesage, & Litz, 2009). Extensions to this work propose an identification method performing optimal partitioning of concurrent subsystems for distributed fault detection purposes (Roth, Lesage, & Litz, 2010).

Regarding Input-Output identification, in (Estrada, Lesage, & Lopez, 2014) the system behaviour, captured as an I/O sequence is processed to obtain Interpreted Petri nets including cyclic behaviour. Although the proposed methodology is scalable due to the algorithms efficiency, the obtained models are close to finite automata and can be huge, due to the explicit representation of observed input changes that could not be relevant to define the output evolution. Later in (Estrada, Lopez, & Lesage, 2015) a new method for building IPN models from I/O sequences is presented. It consists of two complementary stages; the first one obtains, from the I/O sequence, the reactive part of the model composed by observable places and transitions. Afterwards, The I/O sequence is mapped into a sequence of the created transitions, from which the second stage builds the non-observable part of the model including places that ensure the reproduction of the observed input output sequence.

Recently, in (Rodriguez, Tapia, & Lopez, 2016) a novel method allows building a reduced representation of the observable part of the model which yields consequently, a reduced complete IPN.

Other works on the matter, based on different approaches have been proposed. The techniques for workflow mining, published by van der Aalst and co-workers (Cook et al., 2004; van der Aalst, Weijters, & Maruster, 2004), allow building Petri net models of workflow processes in which all the activities are observable. Other works pursue

the construction of a stochastic PN from recorded event sequences (Ould El Medhi, Leclercq, & Lefebvre, 2006; Ould El Medhi et al., 2012).

2. Petri Nets and Automated Modelling

This section presents the basic concepts and notation of Petri Nets (PN) and Interpreted Petri nets (IPN).

Definition 1: An ordinary Petri Net structure G is a bipartite digraph represented by the 4-tuple $G = (P, T, Pre, Post)$ where: $P = \{p_1, p_2, \dots, p_{|P|}\}$ and $T = \{t_1, t_2, \dots, t_{|T|}\}$ are finite sets of vertices named places and transitions respectively; $Pre(Post): P \times T \rightarrow \{0, 1\}$ is a function representing the arcs going from places to transitions (from transitions to places).

The incidence matrix of G is $W = W^+ - W^-$, where $W^- = (w_{ij}^-)$; $w_{ij}^- = Pre(p_i, t_j)$; and $W^+ = (w_{ij}^+)$; $w_{ij}^+ = Post(p_i, t_j)$ are the pre-incidence and post-incidence matrices respectively.

A marking function $M: P \rightarrow Z^+$ represents the number of tokens residing inside each place; it is usually expressed as a $|P|$ -entry vector. Z^+ is the set of nonnegative integers. In particular, in this paper $M: P \rightarrow \{0, 1\}$; the PN is referred as 1-bounded or *safe*.

Definition 2: A Petri Net system or Petri Net (PN) is the pair $N = (G, M_0)$, where G is a PN structure and M_0 is an initial marking.

In a PN system, a transition t_j is *enabled* at marking M_k if $\forall p_i \in P, M_k(p_i) \geq Pre(p_i, t_j)$; an enabled transition t_j can be fired reaching a new marking M_{k+1} . This behaviour is represented as $M_k \xrightarrow{t_j} M_{k+1}$. The new marking can be computed as $M_{k+1} = M_k + Wu_k$, where $u_k(i) = 0, i \neq j$, $u_k(j) = 1$; this equation is called the PN state equation. The reachability set of a PN is the set of all possible reachable markings from M_0 firing only enabled transitions; this set is denoted by $R(G, M_0)$.

Now it is defined IPN, an extension to PN that allows associating input and output signals to PN models. This definition is adapted from (David & Alla, 2010).

Definition 3: An interpreted Petri net (IPN) (Q, M_0) is a labelled net structure $Q = (G, \Sigma, \Phi, \lambda, \varphi)$ with an initial marking M_0 where:

- G is a PN structure,
- $\Sigma = \{\alpha_1, \alpha_2, \dots, \alpha_r\}$ is the inputs alphabet,
- $\Phi = \{\beta_1, \beta_2, \dots, \beta_q\}$ is the outputs alphabet,
- $\lambda: T \rightarrow Ev \times C$ is a labelling function of transitions, where

$C = \{C_1, C_2, \dots, C_{|T|}\}$ is the set of input conditions in which every C_i is a Boolean function on Σ ; when a C_i is always true it is denoted as “=1”, and

$Ev = \{Ev_1, Ev_2, \dots\}$ is the set of input events conditions; every Ev_i is a Boolean function of input events, built on Σ ; events are denoted as α_i_0 and α_i_1 for representing that the input value changes from 1 to 0, or from 0 to 1 respectively. A condition Ev_i may not exist; this is denoted as “ ϵ ”.

In an IPN, a transition t_j will be fired if a) t_j is enabled, **and** b) condition C_j is true, **and** c) the event in $E(t_j)$ occurs.

- $\varphi: R(Q, M_0) \rightarrow (Z^+)^q$ is an output function, that associates with each marking in $R(Q, M_0)$ a q -entry output vector, where $q = |\Phi|$ is the number of outputs. φ is represented by a $q \times |P|$ matrix, such that if the output symbol β_i is present (turned on) every time that $M(p_j) \geq 1$, then $\varphi(i, j) = 1$, otherwise $\varphi(i, j) = 0$.

The state equation of PN is completed with the marking projection $Y_k = \varphi M_k$, where $Y_k \in (Z^+)^q$ is the k -th output vector of the IPN.

Definition 4: A place $p_i \in P$ is said to be *observable* if the i -th column vector of φ (denoted as $\varphi(\bullet, i)$) is not null. Otherwise it is *non-ob-*

servable. $P = P^{obs} \cup \square P^{nobs}$, and $P^{obs} \cap \square P^{nobs} = \emptyset$; where P^{obs} is the set of observable places and P^{nobs} the set of non-observable places.

3. Input-Output Identification Techniques

The Problem statement considers a DES composed of a Plant and a Programmable Logic Controller (PLC) operating in a closed-loop. It is assumed that the data exchanged between Plant and the PLC consists of binary signals. The input signals of the PLC (outputs of the Plant) are generated by the sensors of the Plant. The output signals of the PLC (inputs of the Plant) control the actuators of the Plant. The external behaviour of such a DES can be observed by the change of values of all input/output (I/O) signals exchanged between the controller and the plant.

The signal values of all inputs and outputs at a given instant j can be arranged to form an I/O vector $I/O(j) = (\alpha_1(j) \alpha_2(j) \dots \alpha_r(j) | \phi_1(j) \phi_2(j) \dots \phi_q(j))^T$. At the end of every PLC cycle, the current value of all Inputs and Outputs can be easily captured and recorded in a data base. Each new observed I/O vector (when at least one I/O changes its value) belongs to an I/O vector alphabet (Estrada et al., 2015).

3.1. Stepwise Method

The identification problem can be stated as follows: given a DES whose only available information is a single observed I/O sequence w arbitrarily large and an accuracy parameter κ , the aim of the identification process is to obtain a safe IPN model (Q, M_0) such that $\mathcal{L}_{out}^\kappa(Q, M_0) = \mathcal{L}^\kappa(S)$. Where $\mathcal{L}_{out}^\kappa$ is the observed language and $\mathcal{L}^\kappa(S)$ is the system language of length κ . The parameter κ is used to adjust the accuracy of the identified model, similarly as proposed in (Klein, et al., 2005).

The I/O vector sequence w is progressively built by adding new observed I/O vectors. Variations

Figure 2. Stages of the identification algorithm

in any of input or output between two consecutive I/O vectors in w are considered as events $\tau(j)$, which are relevant to the identification method in which a string of observed events are computed (Estrada, Lopez, & Lesage, 2014).

The events can be depicted in a more compact way. A symbolic input event $\lambda'(\tau(j))$ is a string representation of the input event vector $\beta(\tau(j))$. I_i-1 denotes the change from 0 to 1 of the input I_i ; similarly, I_i-0 denotes the change from 1 to 0 of the input I_i . $\lambda'(\tau(j))$.

Then for a sequence w , a sequence τ of observed events $\tau(j)$, $\tau = \tau(1) \tau(2) \dots \tau(j) \dots$ is processed. During the process, if the difference between two consecutive I/O vectors has not been observed before, a new event e_j is created ($\tau(j) = e_j$). The main steps of the method are given in the PN diagram of Figure 2.

Example 1: Consider a DES that has three output signals: $\Phi = \{A, B, C\}$ and three input signals $\Sigma = \{a, b, c\}$. The entries of the binary I/O vectors have the following correspondence:

$$\begin{bmatrix} a & b & c & | & A & B & C \end{bmatrix}^T.$$

An I/O sequence is progressively observed. The first measured I/O vector of the DES is:

$$w(1) = \begin{bmatrix} 0 & 0 & 0 & | & 0 & 0 & 0 \end{bmatrix}^T.$$

When a second I/O vector

$$w(2) = \begin{bmatrix} 1 & 0 & 0 & | & 1 & 0 & 0 \end{bmatrix}^T$$

is processed, the event vector

$$\tau(1) = e_1 = \begin{bmatrix} 1 & 0 & 0 & | & 1 & 0 & 0 \end{bmatrix}^T$$

is computed; the input event vector is $\lambda(1) = \begin{bmatrix} 1 & 0 & 0 \end{bmatrix}^T$ and its corresponding symbolic input event is $\lambda'(1) = a-1$, i.e. the rising edge of a .

Figure 3. PN representing e_1

Considering a value $\kappa = 1$, we can compute the first event trace $\tau^1(1) = e_1$. This event trace is related to a transition of the IPN. The IPN constructed after observing two I/O vectors is shown in Figure 3.

When a third I/O vector

$$w(3) = \begin{bmatrix} 1 & 0 & 0 & | & 0 & 0 & 0 \end{bmatrix}^T$$

is processed,

$$\tau(2) = e_2 = \begin{bmatrix} 0 & 0 & 0 & | & -1 & 0 & 0 \end{bmatrix}^T,$$

$\lambda(2) = \begin{bmatrix} 0 & 0 & 0 \end{bmatrix}^T$ and $\lambda'(2) = \varepsilon$ are computed and the model is updated, as shown in Figure 4.

 Figure 4. PN representing the sequence $e_1 e_2$

Until 8th I/O vector, the situation is quite similar: every new event is processed and the model is updated (see Box 1).

When the 9th vector

$$w(9) = \begin{bmatrix} 1 & 0 & 0 & | & 1 & 0 & 0 \end{bmatrix}^T$$

is processed, the event

$$\tau(8) = e_1 = \begin{bmatrix} 1 & 0 & 0 & | & 1 & 0 & 0 \end{bmatrix}^T$$

is computed and the trace $\tau^1(8)$ is identified through Step 3 as an already observed trace e_1 . Since it leads to the same marking than the input place of $t_1^{e_1}$, such a place and the output place of $t_7^{e_7}$ can be merged as shown in Figure 5.

Box. 1.

$$w = \left(\begin{array}{c} \xrightarrow{e_1} \\ \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} \end{array} \begin{array}{c} \xrightarrow{e_2} \\ \begin{bmatrix} 1 \\ 0 \\ 0 \\ 1 \\ 0 \\ 0 \end{bmatrix} \end{array} \begin{array}{c} \xrightarrow{e_3} \\ \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} \end{array} \begin{array}{c} \xrightarrow{e_4} \\ \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \\ 0 \\ -1 \end{bmatrix} \end{array} \begin{array}{c} \xrightarrow{e_5} \\ \begin{bmatrix} 1 \\ 0 \\ 0 \\ 1 \\ 0 \\ 1 \end{bmatrix} \end{array} \begin{array}{c} \xrightarrow{e_6} \\ \begin{bmatrix} 1 \\ 0 \\ 0 \\ -1 \\ 0 \\ -1 \end{bmatrix} \end{array} \begin{array}{c} \xrightarrow{e_7} \\ \begin{bmatrix} 1 \\ 0 \\ 0 \\ -1 \\ 0 \\ 0 \end{bmatrix} \end{array} \begin{array}{c} \xrightarrow{e_8} \\ \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} \end{array} \right)$$

$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$
$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$
$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$
$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$	$\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$

Figure 7. PN corresponding to the whole I/O sequence

Since a cycle is found, leading to an intermediate IPN model shown in Figure 6.

Simultaneously to the creation of the intermediate IPN, more I/O vectors are added to the observed sequence and the PN is updated (see Box 2).

Two more cycles are found in this sequence and intermediate IPN models are created. We show only the PN obtained after finding the second cycle (Figure 7) and its equivalent model transformed by analysing concurrency (Figure 8).

3.2. Two-Phase Method

The purpose in this method is not only to compute an IPN model in which the observed sequence is reproducible, but also to achieve expressivity and compactness in the identified model allowing representing causal relationship and concurrency of the involved operations.

The method consists of two main steps which are outlined below.

Figure 8. Equivalent internal model representing concurrency

Step 1: Discovering the reactive input/output behavior. In this step is determined the observable part of the IPN consisting of subnets, named fragments, composed by observable places labeled with output symbols, and transitions labeled with algebraic expressions of input symbols. From the sequence w , a corresponding sequence of transitions S is obtained.

Step 2: Determining the non-observable part of the IPN and the initial marking M_0 . The sequence S is processed for obtaining causal and concurrency relationships useful for determining the non-observable places that relate the fragments such that S (thus w) can be executed from M_0 .

Observable Behavior

Procedure 1 summarizes the steps of the method to identify the {PLC + Plant} observable behavior. (Estrada, Lopez & Lesage, 2015)

Example 2: The purpose of this system (Figure 9) is to sort parcels according to their size. It has 9 signal sensors from the system: $a_0, a_1, a_2, b_0, b_1, c_0, c_1, k_1, k_2$, and 4 signals to the actuators: A+, A-, B, C. This example has been used in other publications (Estrada, 2014), (Estrada, 2014).

The influence of some input signals over the outputs setting is observed at the same PLC

Procedure 1. Computing the observable IPN components

Input: I/O sequence w

Output: Observable incidence matrix φW and labeling transition function λ

1) Analyze sequence w in order to

- Compute events vector sequence
- Compute elementary events
- Compute Direct and Indirect Causality Matrices
- Construct Output Event Firing Functions
- Find Input events with differed influence

2) Use computed data in the previous step to

- Compute transitions of the IPN and their labeling λ
- Compute observable incidence matrix φW

cycle. In order to discover such an input/output direct relationship, we analyze the relative frequency of the occurrence of both input events IE_i and output events OE_k , with respect to the occurrence of OE_k along the whole sequence of events.

Using computing firing functions of output events can be easily translated into IPN fragments, as shown in Figure 10.

For the *Example 2*, $D = \emptyset$; the computed PN fragments are shown in Figure 11.

The behavior is reproduced by merging such conditions into a unique transition, which is labeled by a firing function computed from individual firing functions of each output event. This is captured in the model as a fusion of IPN fragments as shown in Figure 12.

The corresponding partial model is shown in Figure 13. The inferring procedure which al-

Figure 9. Layout of the system case study

 Figure 10. Rising and falling edges of output O_i

allows discovering the non-observable behavior is described in next section.

Non-Observable Behavior

Once the events and transitions of the net are completely defined, we need to add non-observable

places to translate an aggregation of the non-observable dynamics of the process in such a way that the global PN will reproduce the whole behavior of the system.

Given an observable IPN model whose structure is $G^{obs}=(P^{obs}, T, Pre^{obs}, Post^{obs})$ and a transitions sequence $S = t_1 t_2 \dots t_j \dots \in T^*$ reproducing the I/O sequence w , an ordinary PN structure $G^{nobs}=(P^{nobs}, T, Pre^{nobs}, Post^{nobs})$ that reproduces S and an initial marking M_0 enabling S must be found; (G^{obs}, M_0) must be safe.

Thus, the PN structure of the complete identified model is $G=(P, T, Pre, Post)$ with $P=P^{obs} \cup P^{nobs}$, $Pre=Pre^{obs} \cup Pre^{nobs}$, $Post=Post^{obs} \cup Post^{nobs}$.

Figure 11. IPN fragments for Example 1

Figure 14. Structures that represent $t_a < t_b$ a) shows a causal relationship from t_a to t_b , whereas b) shows a concurrent relationship between t_a and t_b

Example 3 (Cont.): By considering the couples of consecutive non-concurrent transitions in Seq' which in this example is only (t_3, t_5) —, the places: (t_1, t_2)

(t_2, t_3) $(t_3, t_1 t_5)$ $(t_4, t_1 t_5)$ (t_5, t_6) (t_6, t_7) and $(t_2 t_7, t_4)$ are computed. The PN structure and the computed initial marking are shown in Figure 16.

Finally, the identified IPN of the sorting system described in Example 2 is obtained by merging the observable model in Figure 13 and the non-observable model from Figure 16 after applying the places correction. We can also delete non-observable implicit places. Then, the IPN shown in Figure 17 is the final model after the merging; it reproduces w .

FUTURE RESEARCH DIRECTIONS

Several proposals address the duration of activities and waiting times in a discrete event process. Timed PN models are obtained from event sequences whose sampling dates of every event are provided. Relevant works on the matter are (Meda, and Medina, 2011) (Muñoz et al., 2014) (Basile, Chiacchio, and Coppola 2013). Recently, in (Rodríguez, Tapia, & López, 2016) a simple and fast algorithm to identify controlled discrete event processes from timed input-output vector sequences has been presented. The method is based on a three-stage strategy: 1) the observable components of the TTIPN are first obtained, 2) the

non-observable part is inferred, and 3) the time parameters associated to transitions are obtained.

Additionally, other important issues regarding the PN structure have to be dealt for discovering the relative frequency of occurrence among the sub-processes represented in a PN model. It is interesting to know the sequencing of such sub-processes or at least the branching factor in alternative production sequences. Figure 18a shows a simple PN model involving two alternative sub-processes. In Figure 18b the model is complemented with a loop formed by p6 and p7, which states a policy that alternates the execution of the internal processes.

CONCLUSION

Identification methods that yield Petri net models have been overviewed. They can be used as automated modelling technique for reverse engineering of unknown or ill known processes. Two input-output black-box methods for PLC-based controlled plants have been presented. First, a stepwise method builds detailed PN models is outlined. The identified model represents the effect of every event in the IPN; this causes huge models close to finite automata. Second, a two-phase method yielding more compact models is described. The separation between the observable and the internal behaviour is clearer allowing a more comprehensible description of causal and concurrent relations among the events. Both approaches require long observations to obtain approximations closer to the actual system behaviour.

KEY TERMS AND DEFINITIONS

Discrete Event Model: Accurate representation of the system behaviour expressed in a fine formalism, usually a finite automaton or a Petri net.

Discrete Event Systems: A class of dynamical systems in which the behaviour is characterised by successions of steady states delimited by events in general asynchronous.

Identification Methods: Techniques that build systematically formal models from the observation of external behaviour.

Input-Output Identification: Identification approach based on input-output sequences observed from a discrete event process.

Petri Nets: Formalism for specifying discrete event systems behaviours, allowing describing states, events, causal and concurrent relations, information exchange, resource allocation, and other complex behaviours.

Research and Development on Software Testing Techniques and Tools

S**Tamilarasi T***VIT University, India***M. Prasanna***VIT University, India*

INTRODUCTION

Software testing is the process of executing the program with the intent of finding the error. It is done to check if the system meets the requirements specified and be executed successfully in the intended environment. Testing checks the system whether it is “Fit for Purpose”, also verifies whether the system does what it is expected to do. Software testing techniques are the different approaches and ways of ensuring that a software application is fully tested. Now days we can get lots of Software Testing Tools in the market. Selection of tools is totally based on the project requirements & commercial or free tools (Open Source Tools) you are interested. Off Course, free Testing Tools may have some limitation in the features list of the product, so it's totally based on what are you looking for & is that your requirement fulfil in free version or go for paid Software Testing Tools.

BACKGROUND

As software applications get more ever complex and intertwined and with the large number of different platforms and devices that need to be tested. Software testing techniques encompass everything from unit testing individual modules, integration testing an entire system to specialized forms of testing such as security and performance

[1]. Testing is a process used to help identify the correctness, completeness and quality of developed computer software. With that in mind, testing can never completely establish the correctness of computer software. One definition of testing is “the process of questioning a product in order to evaluate it”, where the “questions” are things the tester tries to do with the product, and the product answers with its behavior in reaction to the probing of the tester.

SOFTWARE TESTING TECHNIQUES

Testing Outlook

Testing outlook has an impact on the software testing process. Consider the following definition:

Testing is the process to prove that the software works correctly.

This definition sounds good, but the person who developed the software will only try to show that the software works correctly. This is the typical psychology of testing. The software will work correctly for the inputs that are given by that person which will obtain correct results. If some other input was given, the software will obtain wrong results which is not acceptable in a commercial environment.

Now consider this definition:

Testing is a process to prove that the software does not work.

If the aim of the test engineer is to prove that the software does not work, then the process can be considered as good. If the software performs well, then you can say that the software is very reliable. If the software works efficiently, after some days of testing, it does not mean that the software has no bugs at all.

So the definition would be:

Testing is the process to detect the defects and minimize the risk associated with the residual defects.

Verification and Validation

While going for testing, the two terms verification and validation have to be differentiated. Barry Boehm defines these terms as follows:

- **Verification:** “Are we Building the product right?”
- **Validation:** “Are we building the right product?”

Verification is done by the development team to ensure that the software is as per the specifications in the SRS document. It is to check whether the software conforms to specifications. Validation is to check whether the software meets the customer expectations. It is carried out with the involvement of the client.

Levels of Testing

Unit Testing

Unit testing aims at testing each of the components that a system is built upon. As long as each of them works as they are defined to, then the system as a whole has a better chance of working together. Where possible, all units that could

possibly fail are tested at least one. Judgment is needed to decide what parts need testing. Some things such as accessors/mutators generally don't need to be tested. Components that are erroneous can be detected earlier. The scope of unit tests is even smaller than your traditional tests. If errors are detected, they are generally easier to fix.

Integration Testing

The purpose of integration testing is to verify the functional, performance, and reliability between the modules that are integrated. It is a software development process which program units are combined and tested as groups in multiple ways. In this context, a unit is defined as the smallest testable part of an application. Integration testing can expose problems with the interfaces among program components before trouble occurs in real-world program execution. Integration testing is component of Extreme Programming (XP), a pragmatic method of software development.

System Testing

- In system testing the behavior of whole system/product is tested as defined by the scope of the development project or product.
- It may include tests based on risks and/or requirement specifications, business process, use cases, or other high level descriptions of system behavior, interactions with the operating systems, and system resources.
- System testing is most often the final test to verify that the system to be delivered meets the specification and its purpose.
- System testing is carried out by specialists testers or independent testers.
- System testing should investigate both functional and non-functional requirements of the testing.

Acceptance Testing

Acceptance testing, a testing technique performed to determine whether or not the software system has met the requirement specifications. The main purpose of this test is to evaluate the system's compliance with the business requirements and verify if it has met the required criteria for delivery to end users. The acceptance test cases are executed against the test data or using an acceptance test script and then the results are compared with the expected ones.

Test Plan

Test planning, the most important activity to ensure that there is initially a list of tasks and milestones in a baseline plan to track the progress of the project. It also defines the size of the test effort. It is the main document often called as master test plan or a project test plan and usually developed during the early phase of the project.

Test Oracles

Oracle is a repository or knowledge. Test oracles are the people used to check the correctness of the program for the given test cases. Human test oracles are used extensively if the program does not work. A common way is to give the program and the input test data to a friend and ask them to derive the output from the program. If the output is same as expected, then it is said to be correct, otherwise there is a defect in the software.

Test Cases

A test case is a document, which has a set of test data, preconditions, expected results and postconditions, developed for a particular test scenario in order to verify compliance against a specific requirement.

Typical Test Case Parameters

- Test Case ID
- Test Scenario
- Test Case Description
- Test Steps
- Prerequisite
- Test Data
- Expected Result
- Test Parameters
- Actual Result
- Environment Information
- Comments

TEST DESIGN TOOLS

Test design tools help to create test cases, or at least test inputs (which is part of a test case). If an automated oracle is available, then the tool can also make the expected result, so in point of fact it can generate test cases.

Agile Designer

Agile Designer is a one stop shop for requirements definition and test cases. Agile Designer lets you design the perfect set of *test cases*, find and make the 'right' data, link expected results to tests and data, cut defect creation by up to 95% and build clearly-defined outsourcing work packages from visual flows:

- Maximize Test Coverage
- Manage Changing Requirements
- Find and Make Test Data
- Continuous Integration
- Service Virtualization Testing
- Link Expected Results
- Agile Processes
- Optimize Software Tests
- Reduce Software Testing Costs

- Manage Software Outsourcing
- Estimate Development Costs
- Reverse Engineer Requirements

Bender RBT Test Case Design Tool

Bender RBT has two test design engines: Cause-Effect Graphing and Pair Wise. The Graphing engine is the only test tool that designs tests that ensure that defects are propagated to an observable point. Its tests maximize coverage while minimizing the number of tests. It does a logical consistency check on the requirements and can generate an as built spec from the test model - critical for agile projects. The Pair Wise engine supports both orthogonal pairs and optimized pairs. Both engines do strong negative testing.

Coronys Test Automation Framework

Framework comprises real-time test execution engine, script development environment, test flow drag-and-drop creation, test management. Programmable asynchronous events on communication channels are supported for protocol emulation, data capturing and CLI automation. Serial, Telnet, TCP, UDP, HTTP and more protocols are instrumented. DLL, ActiveX, COM-objects are easily integrated into scripts. Test cases aggregated into suites are launched as jobs targeted to specific setups. Incorporate job launch directives into the software build to enhance your Continuous Integration Process. Built-in MySQL database enables querying for in-depth results analysis.

LOAD AND PERFORMANCE TESTING TOOLS

In client/server applications, many users access the server application simultaneously. In such a case, the software has to be tested for its performance.

A speedy and responsive site is directly correlated with higher levels of visitors and better user experience. *Performance testing* plays a vital role. It is the only way to determine an application's behaviour at different levels of load and users.

1. WebLOAD
2. LoadComplete
3. Apache JMeter
4. LoadRunner

WebLOAD

Load and performance testing tool for web applications. WebLOAD lets you perform load and stress testing on any internet application using Ajax, Adobe Flex, .NET, Oracle Forms, HTML5 and many more technologies. You can generate load from the cloud and on-premises machines. WebLOAD's strengths are its ease of use with features like DOM-based recording/playback, automatic correlation and JavaScript scripting language. The tool supports large-scale performance testing with heavy user load and complex scenarios, and provides clear analysis on the functionality and performance of the web application.

LoadComplete

Easy and affordable performance testing tool. LoadComplete enables you to create and execute realistic load tests for websites and web apps. It automates creating realistic load tests by recording user interactions and simulating these actions with hundreds of virtual users either from your local computers or from the cloud. LoadComplete helps you check your web server's performance under a massive load, determine its robustness and estimate its scalability. It also provides detailed metrics and reports that help you get in-depth insights into infrastructure performance, application behavior, and end user experience.

Apache JMeter

Open source load testing tool. It is a Java platform application. It is mainly considered as a performance testing tool and it can also be integrated with the test plan. In addition to the load test plan, you can also create a *functional test plan*. This tool has the capacity to be loaded into a server or network so as to check on its performance and analyze its working under different conditions. Initially, it was introduced for testing the web applications, but later its scope had widened. It is of great use in testing the functional performance of the resources such as Servlets, Perl Scripts and JAVA objects.

HP LoadRunner

This is a HP product which can be used as a performance testing tool. This can be bought as a HP product from its HP software division. Also, it is very much useful in understanding and determining the performance and outcome of the system when there is actual load. One of the key attractive features of this testing tool is that, it can create and handle thousands of users at the same time. This tool enables you to gather all the required information with respect to the performance and also based on the infrastructure.

TEST MANAGEMENT TOOLS

Features or characteristics of test management tools are:

- To manage the tests (like, keeping track of the same kind of data for a given set of tests, knowing which tests need to run in a common environment, number of tests planned, written, run, passed or failed);
- Scheduling of tests to be executed (manually or by a test execution tool);

- Managing the testing activities (time spent in test design, test execution, whether we are on schedule or on budget);
- Traceability of tests, test results and defects to requirements or other sources;

qTest

Developed by QASymphony, qTest is the only test management solution that allows you to manage your manual, exploratory, and automated testing in a single location, providing the most complete view of your testing coverage and progress on the market. With the help of qTest Connector, it has seamless integrations with JIRA for an entire end-to-end QA solution – but that is not all, it also integrates with other tools like Bugzilla, FogBugz, Rally, VersionOne etc.

PractiTest

An entirely SaaS end-to-end QA and Agile friendly Test management tool. Using their unique and customizable filters you can efficiently organize your requirements, create and run tests, track bugs and generate reports using this tool. It integrates seamlessly with leading bug tracking tools like JIRA, Pivotal tracker, Bugzilla, and Redmine as well as various automation tools such as Selenium, Jenkins etc. However, their API can ensure further customizing for your process' needs. It is not open sourced but is quite affordable. You can benefit from their human methodological support throughout your usage.

Zephyr

Zephyr products are the fastest growing agile test management products in the world with more than 7000 customers in 100 countries. Their real-time solutions offer seamless integrations with tools project teams are already using today like JIRA, Selenium, Jenkins, Bamboo as well as the tools

they will use tomorrow as Agile and DevOps processes evolve overtime.

Test Collab

Test Collab is a modern test management tool which offers complete platform for your application's testing. It offers state-of-the-art integration with all popular bug trackers and test automation tools. Apart from that, it offers time tracking, agile methodology, requirements management, test plans and scheduling.

SOURCE CODE TESTING TOOLS

Source code testing tools are specific to the programming language used for developing the software. As UNIX/ Linux is nowadays used for software development extensively. Lint, a utility used to test the portability of the code. Line profilers used to do the timing analysis. These profilers find out the execution time for the entire program as well as for individual function calls.

EMMA Tool

Emma distinguishes itself from other tools by going after a unique feature combination: development while keeping individual developer's work fast and iterative. Such a tool is essential for detecting dead code and verifying which parts of an application are actually exercised by the test suite and interactive use.

CodeCover Tool

CodeCover is an extensible open source code coverage tool. It provides several ways to increase test quality. It shows the quality of test suite and helps to develop new test cases and rearrange test cases to save some of them. So we get a higher quality and a better test productivity. The main features of CodeCover are: Supports statement coverage,

branch coverage, loop coverage and strict condition coverage; Performs source instrumentation for the most accurate coverage measurement; CLKI interface, for easy use from the command line; Ant interface, for easy integration into an existing build process; Correlation Matrix to find redundant test cases and optimize your test suite.

EvoSuite

To find defects in software, one needs test cases that execute the software systematically, and oracles that assess the correctness of the observed behavior when running these test EvoSuite is a tool that automatically generates test cases with assertions for classes written in Java code. To achieve this, EvoSuite applies a novel hybrid approach that generates and optimizes whole test suites towards satisfying a coverage criterion

JavaCodeCoverage (JaCoCo)

JavaCodeCoverage is a byte-code analyzer tool for test coverage analysis for Java software which neither requires neither the language grammar nor the source code. An important aspect of JavaCodeCoverage is that it stores the coverage information for individual test case thereby facilitating detailed coverage analysis. Another important aspect of JavaCodeCoverage is that it records all vital code elements and test coverage information in open source database software MySQL.

DATA FLOW TESTING

Data flow testing can be performed at two conceptual levels: Static data flow testing, Dynamic data flow testing.

Data Flow Graphs

The data flow graph is a graph consisting of nodes and directed links.

Data Object State and Usage

Data Objects can be created, killed and used. They can be used in two distinct ways: (1) In a Calculation (2) As a part of a Control Flow Predicate. The following symbols denote these possibilities:

1. **Defined:** d - defined, created, initialized etc.
2. **Killed or Undefined:** k - killed, undefined, released etc.
3. **Usage:** u - used for something (c - used in Calculations, p - used in a predicate).

1. Defined (d)

- An object is defined explicitly when it appears in a data declaration.
- Or implicitly when it appears on the left hand side of the assignment.
- It is also to be used to mean that a file has been opened.

2. Killed or Undefined (k)

- An object is killed or undefined when it is released or otherwise made unavailable.
- When its contents are no longer known with certitude (with absolute certainty / perfectness).

3. Usage (u)

- A variable is used for computation (c) when it appears on the right hand side of an assignment statement.

Data Flow Anomalies

An anomaly is denoted by a two-character sequence of actions. For example, ku means that the object is killed and then used, whereas dd means that the object is defined twice without an intervening usage. What is an anomaly depends on the application. There are nine possible two-letter combinations for d, k and u. Some are bugs, some are suspicious, and some are okay.

1. **dd:** Probably harmless but suspicious. Why define the object twice without an intervening usage?
2. **dk:** Probably a bug. Why define the object without using it?
3. **du:** The normal case. The object is defined and then used.
4. **kd:** Normal situation. An object is killed and then redefined.
5. **kk:** Harmless but probably buggy. Did you want to be sure it was really killed?
6. **ku:** A bug. The object does not exist.
7. **ud:** Usually not a bug because the language permits reassignment at almost any time.
8. **uk:** Normal situation.
9. **uu:** Normal situation.

In addition to the two letter situations, there are six single letter situations.

1. **-k:** Possibly anomalous because from the entrance to this point on the path, the variable had not been defined. We are killing a variable that does not exist.
2. **-d:** Okay. This is just the first definition along this path.
3. **-u:** Possibly anomalous. Not anomalous if the variable is global and has been previously defined.
4. **k-:** Not anomalous. The last thing done on this path was to kill the variable.
5. **d-:** Possibly anomalous. The variable was defined and not used on this path. But this could be a global definition.
6. **u-:** Not anomalous. The variable was used but not killed on this path. Although this sequence is not anomalous, it signals a frequent kind of bug. If d and k mean dynamic storage allocation and return respectively, this could be an instance in which a dynamically allocated object was not returned to the pool after use.

Data Flow Anomaly State Graph

Data flow anomaly model prescribes that an object can be in one of four distinct states:

1. **K:** Undefined, previously killed, does not exist.
2. **D:** Defined but not yet used for anything.
3. **U:** Has been used for computation or in predicate.
4. **A:** Anomalous.

These capital letters (K,D,U,A) denote the state of the variable and should not be confused with the program action, denoted by lower case letters.

Forgiving Data: Flow Anomaly Flow Graph

Forgiving model is an alternate model where redemption (recover) from the anomalous state is possible. The point of showing you this alternative anomaly state graph is to demonstrate that the specifics of an anomaly depends on such things as language, application, context, or even your frame of mind. In principle, you must create a new definition of data flow anomaly (e.g., a new state graph) in each situation.

Data Flow Strategies

Various types of data flow testing strategies in decreasing order of their effectiveness are:

1. **All - du Paths (ADUP):** The all-du-paths (ADUP) strategy is the strongest data-flow testing strategy discussed here. It requires that every du path from every definition of every variable to every use of that definition be exercised under some test. The all-du-paths strategy is a strong criterion, but it does not take as many tests as it might seem at first because any one test simultaneously satisfies the criterion

for several definitions and uses of several different variables.

2. **All Uses Strategy (AU):** The all uses strategy is that at least one definition clear path from every definition of every variable to every use of that definition be exercised under some test. Just as we reduced our ambitions by stepping down from all paths (P) to branch coverage (C2), say, can reduce the number of test cases by asking that the test set should include at least one path segment from every definition to every use that can be reached by that definition.
3. **All P-Uses/Some C-Uses Strategy (APU+C):** For every variable and every definition of that variable, include at least one definition free path from the definition to every predicate use; if there are definitions of the variables that are not covered by the above prescription, then add computational use test cases as required to cover every definition.
4. **All C-Uses/Some P-Uses Strategy (ACU+P):** The all c-uses/some p-uses strategy (ACU+P) is to first ensure coverage by computational use cases and if any definition is not covered by the previously selected paths, add such predicate use cases as are needed to assure that every definition is included in some test.
5. **All Definitions Strategy (AD):** The all definitions strategy asks only every definition of every variable be covered by at least one use of that variable, be that use a computational use or a predicate use.
6. **All Predicate Uses (APU), All Computational Uses (ACU) Strategies:** The all predicate uses strategy is derived from APU+C strategy by dropping the requirement that we include a c-use for the variable if there are no p-uses for the variable. The all computational uses strategy is derived from ACU+P strategy by dropping the requirement that include a p-use for the variable if there are no c-uses for the variable.

LOGIC BASED TESTING

“Logic” is one of the most often used words in programmers’ vocabularies but one of their least used techniques. Boolean algebra is to logic as arithmetic is to mathematics. Without it, the tester or programmer is cut off from many test and design techniques and tools that incorporate those techniques.

Knowledge Based System

- The *Knowledge-Based System* (also expert system or “artificial intelligence” system has become the programming construct of choice for many applications that were once considered very difficult.
- Knowledge-based systems incorporate knowledge from a knowledge domain such as medicine, law, or civil engineering into a database. The data can then be queried and interacted with to provide solutions to problems in that domain.
- One implementation of knowledge-based systems is to incorporate the expert’s knowledge into a set of rules. The user can then provide data and ask questions based on that data.
- The user’s data is processed through the rule base to yield conclusions (tentative or definite) and requests for more data. The processing is done by a program called the *inference engine*.
- Understanding knowledge-based systems and their validation problems requires an understanding of formal logic.
- Decision tables are extensively used in business data processing; Decision-table preprocessors as extensions to COBOL are in common use; boolean algebra is embedded in the implementation of these processors.

Decision Tables

- It consists of four areas called the condition stub, the condition entry, the action stub, and the action entry.
- Each column of the table is a rule that specifies the conditions under which the actions named in the action stub will take place.
- The condition stub is a list of names of conditions.

The rule specifies whether a condition should or should not be met for the rule to be satisfied. “YES” means that the condition must be met, “NO” means that the condition must not be met, and “I” means that the condition plays no part in the rule, or it is immaterial to that rule. The action stub names the actions the routine will take or initiate if the rule is satisfied. If the action entry is “YES”, the action will take place; if “NO”, the action will not take place. “Condition” is another word for predicate. Decision-table uses “condition” and “satisfied” or “met”. Let us use “predicate” and TRUE/FALSE. Now the above translations become:

- Action 1 will be taken if predicates 1 and 2 are true and if predicates 3 and 4 are false (rule 1), or if predicates 1, 3, and 4 are true (rule 2).
- Action 2 will be taken if the predicates are all false, (rule 3).
- Action 3 will take place if predicate 1 is false and predicate 4 is true (rule 4).

In addition to the stated rules, we also need a *Default Rule* that specifies the default action to be taken when all other rules fail.

Decision Table Processors

Decision tables can be automatically translated into code and, as such, are a higher-order language.

If the rule is satisfied, the corresponding action takes place. Otherwise, rule 2 is tried. This process continues until either a satisfied rule results in an action or no rule is satisfied and the default action is taken. Decision tables have become a useful tool in the programmers kit, in business data processing.

CONCLUSION

Testing has been widely used as a way to help engineers develop high-quality systems by means of small group of programmers to an organized discipline in software engineering. However, the maturation of testing techniques has been fruitful, but not adequate. Pressure to produce higher-quality software at lower cost is increasing and existing techniques used in practice are not sufficient for this purpose. Fundamental research that addresses the challenging 15 problems, development of methods and tools, and empirical studies should be carried out so that we can expect significant improvement in the way we test software.

FUTURE RESEARCH DIRECTIONS

Researchers should demonstrate the effectiveness of many existing techniques for large industrial software, thus facilitating transfer of these techniques to practice. The successful use of these techniques in industrial software development will validate the results of the research and drive future research. Development of efficient testing techniques and tools that will assist in the creation of high-quality software will become one of the most important research areas in the near future.

KEY TERMS AND DEFINITIONS

Agile Processes: Introduce Agile processes into your Software Development life cycle.

Continuous Integration: Manage continuous integration frameworks easily.

Estimate Development Costs: Prevent scope by accurately estimate the cost of new software development and changes to existing systems.

Find and Make Test Data: Reduce the time needed to find and make test data by up to 95%. Link the right data to test cases and expected results.

Link Expected Results: Link expected results to both test cases and data.

Manage Changing Requirements: Significantly reduce the amount of time software testers spend manually repairing existing test cases when a change is made.

Manage Software Outsourcing: Provide a systematic way of enforcing SLAs with out-sourcers.

Maximize Test Coverage: Go beyond combinatorial and pairwise testing and cover 100% of requirements in the smallest number of tests.

Optimize Software Tests: Optimize software tests and clean up your existing test cases, reducing your current test cycles by more than 30%.

Reduce Software Testing Costs: Reduce the cost of testing by de-duplicating your existing test cases and automatically creating missing test cases.

Reverse Engineer Requirements: Define your software requirements using Agile Designer and present them in a visual and active flow chart.

Service Virtualization Testing: Maximise the use of virtualization toolkits by designing the correct request/response sets.

The Role of Feedback in Software Process Assessment

Zeljko Stojanov

University of Novi Sad, Serbia

INTRODUCTION

Processes play a pivotal role in business success of enterprises because effective processes increase their adaptability, efficiency and competitiveness in a global market (Lam, 2014). Lepmets et al. (2012) argued that effective software organizations should align their processes to overall business goals and goals on the operational level, which assumes continuous process assessment and improvement. However, in many cases processes are not well defined, which lead to poor and unsystematic implementation. According to Persse (2006), an organization that uses weak or misdirected processes will have weak products and services, and unpredictable outcomes of business activities. For solving problems with poorly defined and implemented processes, a number of approaches have been proposed and shaped in software process improvement (SPI) frameworks. SPI is a set of activities aimed at achieving better process performance, leading to increased quality of software products and services. However, analysis of reported SPI studies revealed a great variability in success of SPI initiatives (Rainer & Hall, 2003; Montoni & da Rocha, 2014). In addition, Bannerman (2008) argued that implementation of SPI initiatives does not always lead to business benefits.

Process assessment helps software organizations to improve themselves through identification of critical problems and appropriate improvement opportunities. Process assessment is the first phase in SPI cycle, which means that assessment

outcomes serve as input for process improvement action plans. Effective assessment requires commitment and involvement of management at all levels in an organization, as well as involvement of staff who implement processes (Mathiassen et al., 2005; Herranz et al., 2013). According to Baddoo et al. (2000), a variety of experiences and attitudes of different groups of people within an organization positively contribute to realization of process assessment and improvement activities. O'Connor & Basri (2012) stated that people involvement in assessment and improvement activities is necessary because employees are the best source of information for these activities and should implement improvements in practice.

Feedback is one of the most valuable tools for achieving continuous organizational development and improvement (Roebuck, 1996). Feedback is essential in assessing and improving organization performance since it is in the core of problem solving activities and it influences decision making while searching for solutions for identified problems (Greve, 2010). Understanding feedback and its effects requires looking at intrinsic sources of information relevant for increasing knowledge and improving performance of individuals and organizations (Greller & Herold, 1975). Considering people as the main sources of feedback information in an organization positively influences the success of improvement initiatives. However, it is necessary to consider and weight potential sources of information, which is usually the task of people within an organization.

Software process assessment includes feedback as a core activity aimed at feeding data back to relevant individuals or groups within an organization. Feedback is usually a part of a typical sequence of activities, which includes collecting, analyzing and interpreting data. Dyba et al. (2004) proposed a measurement and feedback process in the context of software process assessment with the following steps: planning to use data, collecting data, analyzing data, feeding back data, and follow up. Feedback is also used as a method for learning in software organizations based on previous experiences. Heikkilä (2009) suggested that SPI initiatives should be more concerned with organizational learning and change management, which helps in improving processes gradually and based on lessons learned during SPI implementation. In addition, information included in feedback can be used as a basis for decision making. According to Halloran (1999), software process assessment and improvement facilitate organizational learning if all relevant information and knowledge is communicated to organisation's members.

BACKGROUND

The concept of feedback has been researched and used in many different fields, including education, management, marketing, professional training, human resource development, medicine and engineering. Feedback is a complex concept originated in systems thinking and cybernetics. Due to the specificity of different fields, the term feedback has been used and interpreted in many ways, which causes that there is no universally accepted definition of feedback in theory and practice. Ramaprasad (1983) provided the most general definition of feedback: *Feedback is information about the gap between the actual level and the reference level of a system parameter which is used to alter the gap in some way*. Examinations of this definition in recent literature revealed that it cues directions for learning and performance improvement in organizations (Hattie & Tim-

perley, 2007). The most common usage of the term feedback in the research on humans relates to presentation of information to individuals regarding different aspects of performance, such as behavior or outcomes (Atkins et al., 2002). Assessment of functional mechanisms of feedback provides more useful and practical information for managers and practitioners than assessment of feedback characteristics (Alvero et al., 2001).

Feedback is strategically important and valuable tool for assessing and improving organizations in highly dynamic, uncertain and competitive business environment. Based on the literature review on various types of feedback in organizations, De-Nisi & Kluger (2000) found that studies reported inconsistent results concerning the effectiveness of feedback. For achieving the best positive effects on performance, and preventing possible negative effects, feedback should be carefully planned and designed. Feedback is generally used for evaluating the level of performance and for indicating improvements. In this sense, feedback is used for identifying a gap between what is observed in the practice and what is expected in improved practice. According to Grafton et al. (2010), the main uses of feedback in organizational context are for: (1) promoting organizational learning, (2) analyzing the impact of past decisions, (3) prompt examination of adopted strategies and targets, and (4) identifying needs for corrective actions. Feedback involves people that provide information and people that interpret provided information. Based on the interpretation of feedback information people make decisions in their organizations. Feedback forms loops between actual performance and established goals. According to Hattie & Timperley (2007), the main purpose of feedback is to reduce divergence between current understandings and performances and proposed objectives.

Types of Feedback

Several approaches for defining and observing feedback can be found in literature. Based on

extensive literature review, Gabelica et al. (2012) differentiate two main types of feedback: (1) *performance feedback*, which is concerned with the outputs of observed tasks, and (2) *process feedback*, which is concerned with information how individuals or the teams perform tasks. Performance feedback can be used for performance assessment and improvement. Govaerts et al (2013) described a cyclic process of performance improvement, which includes feedback. In this process, performance is observed and interpreted within assessment process. This assessment is cognitive process during which an assessor provides a judgment about observed performance. These information is available as feedback that should be correctly interpreted in order to enable performance improvement. Performance assessment activities result with feedback in both quantitative and qualitative formats. According to Gabelica et al. (2012), the following three types of process feedback can be distinguished: (1) *task related feedback*, which is related to information how individuals or groups deal in with tasks within a process, (2) *interpersonal feedback*, which is concerned with social conditions under which a group create and share understanding, and (3) *cognitive feedback*, which refers to cognitive interactions between people in a group.

Sengupta & Te'eni (1993) described advantages of using cognitive feedback compared with outcome or performance feedback. Cognitive feedback relates to information that enhances understanding of observed phenomena and quality of decisions in a given context. Cognitive feedback helps in clarifying past decisions and assists in selecting appropriate decision strategies, providing better control of change implementation within a system. This is very important in projects focused on assessing the state of the practice within organizations and planning and implementing proposed improvements. Outcome feedback, in contrast to cognitive feedback, provides only information about the outcomes of observed process, which is generally insufficient for building comprehensive view and understanding, and therefore leads to

less effective decisions and further improvement actions (Sengupta & Abdel-Hamid, 1993).

Feedback Influence on Motivation and Commitment

According to Locke (1996), people need to check their progress while effectively pursuing to proposed goals. Feedback is essential for achieving proposed goals, which means that based on the observed situation it affects goal persistence, disengagement, and goal change (Fishbach & Finkelstein, 2012). In practice, feedback can be positive and negative, but effective assessment and improvement approaches assume proper use of both positive and negative feedback for achieving proposed improvement goals (Fishbach et al., 2010). Positive feedback encourages people to pursue in proposed direction towards proposed goals, increasing their motivation and commitment. At the other hand, negative feedback should be used for identifying weaknesses, the lack of accomplishments and inconsistencies in improvement. In addition, Vallerand & Reid (1988) suggested that positive feedback increases intrinsic motivation, which is largely mediated by the feelings of competence. Negative feedback can also be motivating through self-regulation process, which can lead to making progress towards reducing discovered discrepancy and pursuing toward stated objectives. According to Van-Dijk & Kluger (2004), positive feedback connected with wishes, and negative feedback connected with obligations, increase motivation and commitment.

Feedback and Learning in Organizations

Feedback, as an important and powerful tool for shaping learning in organizations, should be observed from the perspective of individuals, teams and whole organizations (Gabelica et al., 2012). According to Mausolff (2004), organizational processes are the primary source of learning in an organization, while feedback helps in initiat-

ing and sustaining organizational learning. The purpose of feedback in organizational learning is to provide information on actual implementation and performance of processes and activities (identification of strengths and weaknesses), encouraging critical reflections of involved people and guiding further activities related to practice improvement. According to Argote (2013), context based learning in organizations is usually based on direct experiences and depends on several factors, among which feedback takes significant role. London & Smither (2002) presented person–environment interaction view of feedback processes over time, and stated that individual positive attitude towards feedback, feedback orientation and feedback culture in an organization enhance performance improvement programs and learning within an organization. In addition, in the context of performance improvement and organizational learning, feedback is not isolated event but an intrinsic part of comprehensive management process over long period of time. Performance feedback that promotes and facilitates organizational learning should be based on meaningful and sensitive communication between individuals at all organizational levels (Mayfield & Mayfield, 2012). Furthermore, feedback understanding should be enhanced by using consistent feedback terminology and appropriate transmission media.

FEEDBACK IN SOFTWARE PROCESS ASSESSMENT

Performance assessment evolved from a purely measurement based focus to one that recognizes the importance of social and cognitive processes in organizations (Levy & Williams, 2004). Assessment activities are usually implemented within an organization and highly depend on the context that should be completely understood in order to maximize positive outputs. Effective performances of processes require access to relevant information, which comes from many sources like process performers, management, customers and other

stakeholders (Heidrich et al., 2006). Collecting information from various sources ensures comprehensive view of processes and more reliable assessment aligned with organization's business objectives. Better process performances lead to better organizational performances and increases maturity of an organization (McBride, 2010).

Due to the longevity and complexity of assessment and improvement projects, the following questions deserve special attention (Aaen et al., 2001): how participants in these projects know whether they as individuals and as the whole organization achieve proposed goals, how they know if perceived benefits are realized, and how they know what are the next steps based on the observed state of the project? According to Aaen et al. (2001), feedback is essential for effective management in software process assessment and improvement initiatives because it helps in: obtaining visible results in several important points during project implementation, keeping the effort in the focus, and maintaining motivation, commitments, and legitimacy. Further, Arent et al. (2000) suggested that project (with included processes) assessment, with feedback provided to relevant people in an organization, supports commitment, participation and learning in an organization conducting SPI project.

Presenting Results

Information included in feedback provides the basis for decision making related to revealing the next activities in an assessment and improvement project. During process assessment, feedback can be seen as information provided by stakeholders regarding understanding of the current state and results. According to Atkins et al. (2002), feedback format should be carefully designed in order to enable integration of data that have emergent characteristics and to provide a relevant basis for judgments. Majority of assessment processes use information in both quantitative and qualitative formats, enabling more comprehensive understanding and evaluation of

processes' performances (Brutus, 2010). Feedback results should be presented to all relevant people in an organization, ensuring active participation of employees that are the main source of knowledge. Therefore, their involvement in discussion and interpretation of results is invaluable for the success of assessment project.

Dyba et al. (2004) presented an overview of several techniques for presenting and interpreting assessment results, such as mind maps, brainstorming, tables, diagrams and charts. Stojanov et al. (2013) outlined an assessment approach in which feedback includes information presented to company personnel in the form of trends that are based on statistical analysis of data extracted from the maintenance repository in a small software company. Trends were presented with different types of diagrams (lines, charts, pies) and tables. Zarour et al. (2015) identified feedback sessions as one of the best practical techniques in process assessment aimed at presenting assessment results to organization being assessed. Presenting results in an appropriate way enables their validation, as well as continuous improvement of assessment methods.

Directing and Maintaining Motivation and Commitment

Commitment and motivation play the key roles in process assessment projects, because it is recognized that motivated and supported people are willing to reward greater effort in their work. Arent et al. (2000) pointed out the positive effect of active participation and commitment to assessment project activities and overall SPI process, while Mishra & Mishra (2008) underlined positive effects of periodic feedback sessions on the personnel motivation in assessment projects. Active involvement of organization's staff creates opportunities for maintaining motivation and overcoming many difficulties that may occur during assessment. Dyba & Moe (1999) stressed the importance of active cooperation between employees in an organization and researchers,

which ensures maintaining the focus in assessment project, especially in feedback sessions that serve as an effective tool for analyzing the state and directing further activities. Baddoo & Hall (2002) identified feedback as an important motivating factor for developers and senior managers, which can positively affect implementation of SPI projects. In addition, Baddoo & Hall (2003) discovered the lack of management commitment and the lack of feedback to developers as important de-motivating factors in SPI projects. Better understanding of actual processes through staff involvement in assessment activities helps in sharing experiences and defining more realistic improvements goals, which increases their motivation toward improvement project (von Wangenheim et al., 2006).

Learning in Software Process Assessment

Feedback can be used as a method for learning in an organization based on the previous experiences and identified issues in assessment process. One of the most effective ways to provide information to people in an organization is by using feedback meetings, where employees can interpret collected data and results from analysis, as well as pack and store knowledge in a way suitable for reusing in future software projects (Mishra & Mishra, 2008). According to Dyba et al. (2004), conducting several feedback meetings helps in transforming individual experiences to collective knowledge in a company. Cater-Steel et al. (2006) pointed out that feedback can be used for collecting experiences from organizations participating in assessment projects, which can be used for providing recommendations for these organizations in future projects, as well as for improving assessment methods.

Dyba & Moe (1999) presented two industrial case studies in which participants from software organizations were provided opportunities to analyze, interpret and learn from the assessment results. Feedback to participants was provided

during half-day workshops by using several techniques such as gap analysis, scatter plots, bar charts and histograms. Dyba & Moe (1999) stressed the importance of active participation of company employees, which contributes to better implementation of identified improvements and to learning from the experience. Arent et al. (2000) underlined the significance of learning effect in assessment projects that are based on active involvement of people and on-time feedback provided to relevant stakeholders. In such software organizations, learning occurs at different levels - people learn from each other, positive experiences are transferred between different projects, and managers gain a higher level of professionalism and deeper understanding of practice. Kim et al. (2005) presented an experience factory model for accumulating and utilizing process assessment experiences, which is based on database designed for saving all analyzed data in forms of root words. Collected experiences help in decision making and establishing optimal improvement strategies.

SOLUTIONS AND RECOMMENDATIONS

Success of assessment and SPI projects requires a cross-disciplinary group of assessors that includes researchers and key experts available in software organizations (Pettersson et al., 2008; Feliz, 2012), as well as proper use of feedback during all phases in projects (Takeuchi et al., 2014; Stojanov et al., 2015; Zarour et al., 2015). Due to the complexity of software processes that should be comprehensively investigated, assessment should be based on both quantitative and qualitative data collected in the organizational context (Feliz, 2012, Stojanov et al., 2015). Appropriate and timely analysis, combined with feedback, contribute to the efficiency of assessment, facilitate decision making and identification of the most relevant improvements.

FUTURE RESEARCH DIRECTIONS

S

Software process assessment plays important role in investigating and improving everyday practice in software organizations. However, new trends in organizing work of geographically distributed teams, and recognized importance of human factors, introduce new challenges regarding practical issues that should be investigated and understood. Based on these observations, development of new methods and techniques that will facilitate work of distributed teams of assessors can be expected. These new methods and techniques will be based on the contemporary Internet and mobile technologies. In addition, the complexity of human factors' effects on practice will require creation of multidisciplinary teams that will include experts specialized in disciplines such as sociology, psychology and human resource management.

CONCLUSION

It has been recognized by both industry and research communities that assessment of software processes is necessary for maintaining and increasing the quality of products and services. This requires effective plans and guidelines for conducting assessments, resulting with identification and implementation of the most valuable improvements. Effective communication between people involved in assessment projects is a premise for success. This communication includes preparation and implementation of assessment plans, but also requires the use of efficient feedback techniques in all phases of assessment in order to achieve the best outcomes.

KEY TERMS AND DEFINITIONS

Cognitive Feedback: Information that enhances understanding of observed phenomena and quality of decisions in a given context.

Commitment: The state of being dedicated and focused to do something.

Feedback: Information or individual's responses on difference between actual level and proposed level of a system parameter.

Learning: Activity or process of acquiring knowledge or skills through studying or practical experience.

Motivation: The state when someone desires or is willing to do something.

Performance Feedback: Information about different aspects of performances of a task, a system or individuals, which can be used as a basis for improvement.

Software Process Assessment: A set of activities planned and conducted with the aim to get insight into the current state of software processes.

Software Process Improvement: A set of activities planned and conducted with the aim to achieve better performances of software processes, which leads to higher quality of delivered software products and services, as well as to better organizational performance.

Software Process: A set of activities related to development, maintenance and management of software systems.

Secure Software Development of Cyber–Physical and IoT Systems

S

Muthu Ramachandran

Leeds Metropolitan University, UK

INTRODUCTION

Cyber-Physical Systems (CPS) and Internet of Things (IoT) is on the rapid increase as the demand for such applications is growing exponentially. There is a very strong reason for connecting three technologies such as CPS, IoT and Cloud as the first two are connected to a cloud for receiving and analysing data. Cloud computing has emerged to provide a more cost effective solution to businesses and services while making use of inexpensive computing solutions which combines pervasive, Internet, and virtualisation technologies. Cloud computing has spread to catch up with another technological evolution as we have witnessed Internet technology, which has revolutionised communication and information superhighway. Cloud computing is emerging rapidly and software as a service paradigm is increasing its demand for more services. However, this new trend needs to be more systematic with respect to developing secure software engineering and its related processes such as requirements, design, development, and test. For example, current challenges that are faced with cyber security are: application security flaws and lessons learned which can all be applied when developing applications for CPS and IoT systems. Similarly, as the demand for cloud services increases and so increased importance sought for security and privacy. Cloud service providers such as Microsoft, Google, Sales force.com, Amazon, GoGrid are able to leverage cloud technology with pay-per-use business model with on-demand elasticity by which resources can be expanded or shortened based on service requirements.

Alur (2015) defines CPS as:

“A CPS system is defined as a system consists of computing devices communicating with one another and interacting with the physical world via sensors and actuators.” Examples of such systems include from smart buildings to medical devices to automobiles.

McEwen and Cassimally (2014) defines IoT as:

“An IoT system consists of any physical objects contains controllers, sensors, and actuators are connected with Internet.” Examples of such system include any devices capable of sending and receiving data through the internet such as internet enabled washing machine, dishwasher, etc.

In other words, IoT can also be defined as the network of physical objects or things that are built or embedded with sensors, actuators, software, and connect via the internet which enables these objects to collect and exchange data. The difference between the CPS and IoT needs to be clarified as the applications being deployed over the years. First of all, let us look at a precursor is known as Embedded systems which have been successfully deployed in wider areas such as aerospace, manufacturing, chemical processes, civil infrastructures, etc. The key difference between the CPS and Embedded system is the inter-connectivity of these networked physical objects, whereas it often not embedded but interact with physical world objects. A wireless sensor networks can be mounted around a river to receive and exchange data amongst them to calculate any abnormal level

DOI: 10.4018/978-1-5225-2255-3.ch655

of river overflow to avoid any natural disasters in the region. Therefore, security of CPS and IoT systems are paramount to our research as well as their data has been secured.

Currently, security related flaws are being found on a daily basis that are fixed by adding security patches. This is simply an unacceptable paradigm for sustainability of cloud computing. Therefore, we need to develop and build cloud services with build-in security of services (SaaS, PaaS, IaaS), data centres, and cloud servers. This article aims to provide a number techniques and methods for developing cloud services systematically with build-in security. It will also cover a range of system security engineering techniques have been adopted as part of a cloud development process. A number of examples of scenarios have chosen from Amazon EC2, to illustrate with, emerging cloud system security engineering principles and paradigm (Ramachandran, 2013 & 2014). This real-world case study have been used to demonstrate the best practices on business process modelling and component based design for developing cloud services with Build Security In (BSI). BSI techniques, strategies, and process presented in this article are general systems security principle and are applicable for both in a cloud environment and traditional environment (non-cloud environment). The significant contribution of this research is to illustrate the application of the extended system security method known as SysSQUARE to elicit security requirements, to identify security threats of data as well as integrating build-in security techniques by modelling and simulating business processes upfront in the systems development life cycle.

BACKGROUND

Legacy applications have complex interconnections and are connectionless. For example, a sales manager needed to access a real-time stock on the mainframe applications when travelling requires migrating to SOA. IoT (Internet of Things) has

emerged to address the need for connectivity and seamless integration with other devices. However, there are potential challenges ahead meeting the growing need for IoT based applications. This includes design and implementation challenges, various applications and connectivities such as smart objects and wireless sensor networks, data gathering, storing and analyzing in a cloud based solution, and IoT Security and Privacy issues. Piayre and Seong (2013) discuss an IoT application for a wireless sensor network which is useful in emergency response systems. In addition, CPS systems have a much bigger impact on connected devices, therefore, it is important to understand the clear distinction between these two systems. Table 1 provides features against CPS and IoT systems which considers computational capacity, processing speed, storage capacity, multiple sensor capacity, multiple communication capabilities, mobility, distribution capability, programming, and architectural model that is suitable and secured.

Table 1. Features of CPS and IoT systems

Features	Cyber Physical Systems	IoT
Significant computational capacity	high	low
Processing speed	high	low
Storage capacity	medium	low
Multiple sensory input/output devices, such as touch screens, cameras, GPS chips, speakers, microphone, light sensors, proximity sensors	√	√
Multi-communication connectedness using Wifi, GPS, 3-5G, Bluetooth, etc	√	√
Mobility	Mobile CPS	Mobile
High Level Programming	Java	Java
Distribution Mechanism (Apps Store, Play Store, etc)	√	√
Architectural Design Model	Layer Model, Event-Driven, Web Services	Event-Driven, Web Services

CPS AND IoT ARCHITECTURAL DESIGN CHARACTERISTICS: FUNCTIONS VS. ATTRIBUTES

Design of software architecture for CPS and IoT systems is the key to achieving long term goal of building a sustainable service which is secure and available. There are numerous characteristics that are expected from such devices and their services. Figure 1 shows a five layer model for CPS and IoT architectural layers and their properties. The layers are connection layer 1 (providing plug & play capability as shown at the bottom of the triangle), data analytics layer 2, data mining layer 3, presentation/Cognitive layer 4, and finally a configuration layer 5 (as shown at the top of the triangle providing self configurability and composability of services and devices).

IoT has emerged to address connecting everything possible around us and get real data on behavior otherwise would have not been possible. It all started with RFID technology in the early part of 2000 introduced in the retail market to as product id-tags, in 2010 the technology has been applied to surveillance, healthcare, security, transport, food safety, by 2020 the technology will be used in locating people, products, collecting data on every objects, further on it will be applied in tele-operations and tele-presence, virtual world, touch and feeling, and ability to touch, monitor, and control remote objects, etc.

The following section introduces a systematic approach to developing security specific system requirements for building BSI right from requirements phase of the system engineering life-cycle for IoT and CPS based applications.

Figure 1. CPS and IoT architectural design characteristics

MAIN FOCUS OF THE ARTICLE

Security Requirements Engineering for CPS and IoT Systems

Current examples of UK cyber security attacks on businesses are devastating from Carphone warehouse (a mobile phone sales business), Talktalk (a telephone service provider), and Ashley Madison, a dating website where personal data. Ashford (2009) reports UK business spends 75% of the software development budget on fixing security flaws after delivering the product. This is a huge expenditure and it also creates untrustworthiness amongst customers. Andress (2011) provides an excellent literature survey on the basics of information security techniques. The cyclic security principles known as IAA is not limited pattern of solution for developing secure systems. There are other security concepts that form a pattern of solution known as CIA (Confidentiality, Integrity, and Availability). The CIA considers more towards how well we should design supporting those three characteristics of systems including software and services. In addition, Andress (2011) stated the concept of ParkerianHexad, which consists of six principles CIA (3) + PAU (3) (Possession or control, Authenticity, and Utility).

Traditionally, security has been added and fixed by releasing security patches on a daily basis by major software vendors. This practice needs to change by systematically identifying and incorporating system security right from requirements. This process is known as Building In Security (BSI). Readers are urged to follow the work by McGraw (2004 & 2006) and Ramachandran (2011). This article contributes towards providing a system engineering process for developing and deploying cloud services systematically. It also provides a classification system for cloud security and cloud data security which are useful for developing and maintaining large scale systems with build in security. Finally, data security has been modelled and simulated using the business process methodology. The

results show effectiveness when we develop systems systematically with good systems engineering principles and tools. Therefore, our main recommendation towards building security in (BSI) strategy is to follow one of our guidelines/recommendations:

The aforementioned processes and classification, security principles, and security attributes can be used as a framework for capturing security specific requirements supporting BSI focus by Systems and Software Engineers. In other words, Security requirements = principles of CIA + PAU.

Allen et al. (2008) state that the one of the main goals of Software Security Engineering is to address software security best practices, process, techniques, and tools in every phases and activities of any standard software development life cycle (SDLC). The main goal of building secured software which is defect free and better built with:

- Continue to operate normally in any event of attacks and to tolerate any failure.
- Limiting damages emerging as an outcome of any attacks triggered.
- Build Trust & Resiliency In (BTRI).
- Data and asset protection.

In other words, secured software should operate normally in the event of any attacks. In addition, it involves the process of extracting security requirements from overall system requirements (includes hardware, software, business, marketing, and environmental requirements) and then also further refined and extracted security and software security requirements from software and business requirements. Then the refined software security requirements can be embedded and traced across the software development life cycle (SDLC) phases such as requirements, design, development, and testing. This has not explained well in security related literatures so far. This provides a clear definition of eliciting software security requirements.

Capturing and identifying requirements for security explicitly is one of challenges in software engineering. Often security is considered as one the non-functional requirements which have been considered as constraints identified during and after software has been developed and deployed. However, it has an impact on the functionality of the system. Therefore, we need to be able specify security requirements explicitly throughout the security-specific life-cycle phases as part of achieving BSI (security requirements, design for security, security testing & securability testing). Mead (2005) for the SEI's (software Engineering Institute) has identified a method known as SQUARE (Secure Quality Requirements Engineering) which has been extended SysSQUARE (Systems Engineering SQUARE) towards systems security engineering method. Our extended method consists of nine steps as follow:

- **Agree on Definition:** Which means to define a set of acronyms, definitions, and domain-specific knowledge needs to be agreed by stakeholders. This will help identify and validate security-specific requirements clearly by stakeholders.
- **Identify Security Goals:** Which means to clearly define what is expected of the system with respect to security by business drivers, policies, and procedures.
- **Develop Artefacts:** Which means to develop scenarios, examples, misuse cases, templates for specifications, and forms.
- **Perform Risk Assessments:** Which means to conduct risk analysis for all security goals identified, conduct threat analysis.
- **Select an Elicitation Technique:** Which includes systematic identification and analysis of security requirements from stakeholders in the forms of *interviews, business process modelling and simulations, prototypes, discussion and focus groups*. As part of this phase, one has also to identify level of security, cost-benefits analysis, and organisational culture, structure, and style.
- **Elicit Security Requirements:** Which includes activities such as producing security requirements document based security specific principle structure as part of our goal of developing BSI earlier, risk assessment results, and techniques identifies for analysis such as *business process modelling and simulations, threat modelling, and misuse cases*, etc.
- **Categorise Security Requirements:** Which includes activities such as classifying and categorising security requirements based on company-specific requirements specification templates and to use our recommended security principles as this will help Systems Engineers to apply BSI and track security-specific requirements for validation & verification at all stages of the systems engineering life-cycle.
- **Identify Systems Data Security Requirements:** Which include activities on extracting and carefully identifying data security and relevant sub-systems such as data centres, servers, cloud VM, and software security, SQL security, and other types of security that are relevant to data. This separation of concern allows systems engineers to integrate, track, design, and develop data security as part of enterprise wide systems development.
- **Prioritise Security Requirements:** Which include activities of selecting and prioritising security requirements based on business goals as well as cost-benefit analysis.
- **Inspect Security Requirements:** Which means to conduct requirements validation process using requirements inspection and review meetings.

According to the SysSQUARE model, the first phase starts with identifying security requirements that are achievable and agreed by all stakeholders who are involved in the process. The second step focuses mainly on developing a list all possible security goals as part of the business and functional

Figure 2. CPS and IoT security attributes

goals. Thirdly, to develop a list of artifacts that are needed to achieve those security goals. Fourthly, to conduct a detailed risk assessment for each security goal identified and assessed. Clear identification of requirements of the whole application system and extract security requirements. Interact with stakeholders to clarify security requirements and the technology they want to use, and cost implications. Categorisation and prioritisation of security requirements will help achieve realistic goals against business targets. For example, a network system we need to separate further two categories of security requirements such wired and wireless security systems. The SysSQUARE method elicitation of security requirements has been applied to study the behavior of threat modelling for cloud data security which has been presented in the last section of this article.

Cloud computing has emerged to address the needs of the IT cost-benefit analysis and also a revolution in technology in terms of reduced cost for Internet data and speed. Therefore, the demand for securing our data in the cloud has also increased as a way of building trust for cloud migration

and to benefit business confidence in the cloud technology by cloud providers such as Amazon, Microsoft, Google, etc. Therefore, we also want to make sure our BSI model and strategies are applicable to cloud services as well as traditional systems. Figure 2 shows a model to structure CPS and IoT security attributes to develop and integrate BSI across the system development life-cycle.

The CPS and IoT security attributes shown in Figure 2, are essential and useful to understand non-functional aspects of services development and service provision. These attributes are also useful for building BSI and maintaining security. As shown in the figure, protecting and securing CPS and IoT systems requires energy efficient algorithms, efficient data allocation and retrieval algorithms, and high level of data security using encryption and decryption efficient algorithms. The service availability of these systems is a priority requirement, and often these systems can be developed using readily available APIs such as Google map API, weather forecast APIs, Facebook APIs, Twitter APIs. For example, one could use an IoT to monitor physical premises and send every

data to a Twitter account using those APIs so that relevant people will be alerted quickly.

SOLUTIONS AND RECOMMENDATIONS

Integrated Secure Software Development Paradigm

The above discussed drawbacks and requirements for a concise method, lead us to develop a model that integrates various activities of identifying and analysing software security engineering into the software development process, and this new

process and its activities is shown in Figure 3. However, this paper focuses on only software security requirements specific activities. According to this model, SSRE (software security requirements engineering) consists of identifying standards and strategies of the organization with regards to requirements elicitation (including analysis, validation, verification), conducting risk management and mitigation, and identifying software security requirements consists of a further sub-processes of defining security, identifying security strategies, conducting areas and domain scope analysis, business process modeling and simulation, identifying security issues, applying use cases and misuse cases, attack patterns.

Figure 3. Integrated secure software development engineering life cycle (IS-SDLC)

Likewise, this model also provides security-specific processes for identifying security threats during design, development, testing, deployment, and maintenance. There are a numerous number of good design principles that can be found in a vast majority of software design literatures. However, the following is a list of some of the key design principles that are highly relevant to software security design and are part of our IS-SDLC model:

- Principles of least privilege states to allow only a minimal set of rights (privileges) to a subject that requests access to a resource. This helps to avoid intentional or intentional damage that can be caused to a resource in case of an attack.
- Principles of separation of privilege states that a system should not allow access to resources based on a single condition rather it should be based on multiple conditions which has to be abstracted into independent components.
- Design by incorporating known Common Vulnerability Exposures (CVE, <https://cve.mitre.org/>).
- Design for resilience to develop a resilience model which supports system sustainability along side with Building Trust and Security In (BTSI).
- Select software security requirements after performance simulation using BPMN (Business Process Modeling Notation) and is described in detail by Ramachandran.

SSRE activities in our IS-SDLC supports security in a software defined networking (SDN), Cloud computing services (Software as a service (SaaS), Platform as a Service (PaaS), and Infrastructure as a Service (IaaS), Enterprise security includes cloud service providers and service consumers, and design for security principles and techniques. This the unique contribution of this model and for the body of knowledge in software security research.

Service Component Model for CPS and IoT Systems

The emergence of IoT main purpose is to be highly interoperable and being able to connect to smart objects, virtual objects, non-deterministic network environment, etc. This can only be achieved with such a high degree of interoperability is by design ToT systems on web services and SOA. Therefore, this paper has developed a service component model based on the IoT requirements now and in the future which is presented in Figure 4.

As shown in the Figure 4, service component model provides two types of interfaces requires services shown as semi-arc for accessing input from wireless sensor (IWSN), sensor data (ISensorData), actuator data (IActuator), and environmental data such as location services (IEnvLocData). There are a number of provider services which this component model offers to connect to other services for composing very complex applications. These are IDataAnalytics, ISecurity (a set of attributes for handing secured services in the event of any intrusion), IWebServer and ICloudServer (connecting to web services and cloud services).

FUTURE RESEARCH DIRECTIONS

This article has presented our approach to developing cloud services systematically with build in security. We have developed a number of security-specific components that can be reused and customised because they are components with message interfaces. We have also developed a number of business processes with simulation to pre-inform us about their performances and security measures that can be taken before service implementation and deployment. As we discussed in this article, to make cloud computing as a new technological business model that is highly successful, profitable, and sustainable, we need to ensure cloud security and privacy can be maintained and trusted. Therefore, most

Figure 4. Service component model for CPS and IoT systems

of the future research will focus mainly on cloud security related issues, in particular, some of more specifically:

- CPS and IoT with Cloud Computing.
- CPS and IoT Development, Tools and Techniques.
- CPS and IoT with Big Data Analytics.
- CPS and IoT with Security issues.
- Control of cloud resources where it is being used and shared and their physical security if this is a hardware resource. In other words, *security concerned with sharing resources and services*.
- Seizure of a company because it has violated the local legislative requirement. Concerns of client's data when it has also been violated. Therefore, forensic investigation of cloud services and cloud data recovery and protection issues will dominate much of the future research.
- Consumer switching to price competition. Storage services provided by one cloud vendor may be incompatible with another vendor's service if user decides to move from one to the other (for example, Microsoft cloud is currently incompatible with Google cloud).
- Security key encryption/decryption keys and related issues. Which is a suitable technique for a specific service request and for a specific customer data? Who should control? Consumers or providers?
- Cloud service development paradigm. What is the suitable development paradigm for this type of business driven delivery model?
- CPS and IoT Service security vs. cloud security vs. data security will dominate most of the future research.
- CPS and IoT Privacy related issues. Who controls, personal and transactional information?

- Audit and monitoring: How do we monitor and audit service provider organisations and how do we provide assurance to relevant stakeholders that privacy requirements are met when their Personally Identifiable Information (PII) is in the cloud?
- Engineering CPS and IoT cloud services. How do we develop, test, and deploy cloud services? Can we continue to follow traditional methods and process?
- Business process modelling integrated with cloud service development will emerge and can address business related issues.
- Integrating data security as part of the system, software, and service engineering processes.

CONCLUSION

CPS, IoT, and Cloud computing have established its businesses and providing services for connected devices. However, this new trend needs to be more systematic with respect to software engineering and its related processes. For example, current challenges that are witnessed today with cyber security and application security flaws are important lessons to be learned. It also has provided best practices that can be adapted. Similarly, as the demand for CPS, IoT, and cloud services increases and so increased importance sought for security and privacy. We can build CPS, IoT, and cloud application security from the start of the cloud service development. CPS, IoT, and Cloud computing are multi-disciplinary that includes social engineering, software engineering, software security engineering, distributed computing, and service engineering. Therefore, a holistic approach is needed to build services. We need to use established architectural and service component model that has been proven over the years in many applications.

KEY TERMS AND DEFINITIONS

Build Security In (BSI): The process of identifying service security requirements right from beginning of the service identification to the complete life cycle.

Business Process as a Service (BPaaS): The set of process related to managing process related activities of a service business.

Cloud Data Security (CDS): Security of maintaining and preserving client's data that are kept in the cloud.

Service Reuse: The process of reusing services when composing new services.

Software Security Engineering (SSE): The new discipline of applying engineering principles to develop security requirements to engineer software applications including cloud services such as SaaS is essentially a software application which is delivered as a service.

Software Literacy

S**Elaine Khoo***University of Waikato, New Zealand***Craig Hight***University of Newcastle, Australia*

INTRODUCTION

Software mediates almost every aspect of everyday life. Nearly all of human professional and personal activities are embedded and shaped within systems and interactions that involve software at some level from the seductive ecosystems on devices such as iPhones or iPads through to functional interfaces of automatic teller machines (ATMs), to the tools underlying everyday practices such as word processing and email, through to the sophisticated professional editors for multimedia design. None of these tools are 'neutral'. They derive from social and cultural assumptions about their use and all have particular values embedded in their interfaces and hierarchy of affordances. These embody conceptual frameworks in which particular ways of acting or thinking are more possible and imaginable than others. Despite their ubiquity within contemporary society, software itself is only now emerging as a field of study in its own right. As championed by the proponents of Software Studies this is a vital but neglected area of cultural production intersecting with and potentially shaping all other spheres of cultural, economic and political activity (Fuller, 2008; Livingstone et al. 2014; Manovich, 2008). This article proposes the notion of 'software literacy' as one way to understand the skills and understandings needed for people to be critical and creative users of software (as application, platform and infrastructure) in today's software saturated culture. This contribution argues for the relevancy of software literacy as deeply intertwined with people's engagement with software and how it influences

the way people come to understand, represent, generate and critique knowledge. The discussion below begins by overviewing the background and need for a focus on software studies before proceeding to define, introduce and elaborate on a framework for software literacy. An outline of the framework is then grounded in and exemplified through a case study located within a university teaching and learning context with implications for further thinking and research in the field.

BACKGROUND

The proliferation of digital and networked technologies is an expanding and accelerating feature of modern societies and can be predicted to continue to rise and impact on almost every sphere of human living. Most people develop some level of proficiency with everyday software packages informally through their daily use and incremental engagement over time (Bulfin & Koutsogiannis, 2012; Hague & Logan, 2009). Informal learning practices have been shown to increase students' sense of agency and consequently to have the potential to make learning a richer and more fulfilling experience (Furlong & Davies, 2012). Commenting on the trend of digital penetration, numerous authors have further argued that ubiquitous access to digital technologies has shaped a new internet-centred generation of 'digital natives' (Oblinger, 2003) with the corresponding assumption that access to digital tools has, on its own, facilitated the development of new learning skill sets (Tapscott, 2009). Terms such as the

DOI: 10.4018/978-1-5225-2255-3.ch656

‘digital generation’, ‘millennials’, ‘Net Generation’ (Tapscott, 1999), ‘digital natives’ (Prensky, 2001), ‘Google generation’, ‘Generation Y’ and so forth have derived from a host of assumption about the distinctive skill set of generations immersed within digital technologies. Such labels aim to characterise an emerging class of learners accustomed to engaging with software and technologies such that they can effortlessly adopt new technologies, operate at ‘twitch speed’, are able to multitask, imagine, and visualize while communicating in multiple modalities and consequently possess higher technical skills compared to previous generations (Prensky, 2001). The term ‘digital natives’ itself assumes a generational change in digital literacies fed particularly by informal learning, opinions which are closely informed by emancipatory rhetoric surrounding the digital. Consequently in part the term articulates anxieties amongst educational institutions and practitioners that they are falling behind the literacies students will bring with them to learning contexts.

Educators thus are often encouraged to operate under the assumptions that students already possess the necessary computing skills and conceptual frameworks to learn with and through generic software packages, and tend to neglect the role which the affordances of software themselves play in shaping how students ‘perform’ the software (Adams, 2006). Recent research indicates that such assumptions about students’ digital proficiencies are unfounded and that digital inequalities and marginalization persist around students’ access to, and use of, information and knowledge (Bennett, Maton, & Kervin, 2008; Jones & Czerniewicz, 2010; Kennedy et al., 2008). There is evidence students may not be aware of how to apply software embedded technologies effectively to enhance their learning (Khoo, Johnson, & Zahra, 2012; Valtonen, et al., 2011). In other words, digital inequality may not be defined specifically to the issue of *physical* access to digital tools (software and hardware) but may be intimately shaped by each learner’s ability to learn and apply (software-based) tools in ways

which similarly constrain learning and access to knowledge. A student cohort where everyone has access to digital technologies does not necessarily mean that they have all naturally acquired the literacies to usefully apply and critically engage with those technologies. Inequalities also arise due to differences in the social and cultural support for digital use; the expectation of teaching and learning institutions should perhaps be that individuals may be more or less able to exploit and critique the affordances of software and hardware (Selwyn & Facer, 2007).

For example, common affordances such as copy, cut, and paste are assumed to be naturalized and embedded across different software applications and able to be picked up with ease by this current millennial generation for work and leisure pursuits. However these affordances are also poorly understood as tools contextualized within larger hierarchies of affordances and interfaces that shape both their use and more broadly people’s engagement with knowledge, culture and society in the 21st century (Livingstone, Wijnen, Papaioannou, Costa, & Grandio, 2014).

There is a need to parse the distinctions between distinct media, information and specifically digital-centered literacies relevant to current digital and networked technologies and to examine the nature of student understanding and decision making around which tools might best serve their learning purposes. Labels such as ‘digital natives’ tend to conflate a basic skill in operating new technologies with broader forms of understanding and the ability to critique aspects of technology-based cultures. It is important to challenge these stereotypes and assumed competencies in order to examine the range of skills and other literacies that today’s students bring (and do not bring) to their tertiary learning. Students may not be aware of the full implications of the affordances and constraints offered through particular software; students may be as likely to be ‘captured’ by specific applications as ‘empowered’ by them. The design of software necessarily enables some practices even as it constrains and marginalises

others. An awareness of the nature, rationale and implications of different software becomes more vital in situations where platforms and applications are assumed by their users to be ‘neutral’ tools. Many studies have been conducted on information literacy and on ways of mastering software (Underwood, 2009), but the role of software itself tends to be taken for granted and is not questioned. No studies to date have raised the role of student understanding of how software and its affordances influence knowledge representation, generation, and critique.

Educators know very little about how students develop the skills and expertise needed to attend to the features and use of software (as application, platform, and infrastructure) in the service of completing basic and complex learning tasks. There is evidence that students adopt a range of informal approaches to meet their learning needs due to the proliferation of digital and networked tools (Peeters et al., 2014). Research also indicates that students’ formal software learning backgrounds are diverse (Khoo, Johnson, Torrens, & Fulton, 2011). As with other tools employed during learning, student knowledge and use of software and hardware is highly specific to their formal and informal educational, social, and cultural contexts for learning and use (Jones, Ramanau, Cross, & Healing, 2010; Valtonen, Dillon, Hacklin, & Väisänen, 2010). There is a need for further studies to raise lecturer awareness of the role that software plays in shaping and framing what and how they teach and its effects on student learning. In particular, educators can benefit from ideas and guides that help them to interrogate and reflect on their practice to facilitate more effective pedagogies for teaching and learning with, through and about software (including raising their students’ awareness to similar issues).

SOFTWARE LITERACY

Software studies, a comparatively new field of enquiry, proposes that ‘software’, which encom-

passes many forms of computer programming, is the dominant cultural technology of our time (Fuller, 2008; Johnson, 1997; Manovich, 2013). Manovich argues that we need to ‘think of software as *a layer that permeates all areas of contemporary societies* (emphasis in original, 2013, p. 15), a feature of all cotemporary social and cultural practices which has been comparatively neglected as an object of investigation. In an era in which our daily work routines may revolve around the use of a set of creative and communicative applications, social, cultural and political communication is embedded within software platforms such as Facebook, YouTube and Twitter, and a plethora of software applications run in the background of all major institutions, ‘software’ as a collective needs to become the target of greater investigation. A core premise of software studies is the need to recognise the role of software in shaping the nature of our institutions and our everyday lives; for software users (i.e. the vast majority in modern societies) to develop a more critical awareness of how software operates to both ‘empower and discipline’ people (Kitchin & Dodge, 2011, p. 10-11). For instance, Adams (2007) argues for the development of more informed epistemologies of practice and advocates for software design principles that are more sensitive to pedagogical practices. Others such as van Leeuwen and O’Halloran (2011) underscore the need for software literacy modelling and use by lecturers and students. Being more critically aware of these aspects would allow educators and students more informed use of software (Vallance & Towndrow, 2007). This awareness can lead to opportunities for more equitable exploration and dialogue concerning the social, cultural and technological forces that shape the way in which knowledge within a discipline is developed, shared and communicated, and the implications of these aspects for teaching and learning practices.

In order to extend this line of research the term ‘software literacy’ is proposed and defined as the expertise in understanding, applying, problem solving and critiquing software in pursuit of particular learning and professional goals (Hight,

Khoo, Cowie, & Torrens, 2014). This notion is grounded in a practice-based schema which aims to identify what distinguishes a novice user from an expert user through proposing a progressive transition from novice to expert-like understanding, capabilities and qualities (Jones, 2008; Livingstone, et al. 2014). Three progressive tiers of development towards software literacy exist. They are:

1. A basic skill level where a learner can use a particular software (typically using default affordances),
2. An ability to independently troubleshoot and problem solve issues faced when using the full range of affordances constructed by the software, and finally,
3. The ability to critique the software, including being able to apply such critique to a range of software designed for a similar purpose and to further use these understandings for new software learning.

A key threshold in tier 3 is the point where students are able to transfer a critical understanding of software affordances and use to new software and to familiar software in new contexts and situations. They can be assumed to have the sophisticated understanding needed to then consider how software (at various levels of application, platform and infrastructure) shapes the particular kinds of knowledge and actions that are readily available while at the same time constraining other forms of knowledge and action. At this level, students (and by extension, citizens) are assumed to be capable of recognizing more broadly the role which software plays in various levels within contemporary life, and to more deliberately choose platforms and applications based on a thorough understanding of the conceptual and practical implications of their choices. This third tier accentuates an ability to critique as essential; an attribute also recognised by other researchers as a key characterisation of 21st century learners and working professionals to participate productively in the political, leisure

and social spheres of everyday life (Gilbert 2005; Jenkins et al. 2009).

Developing one's software literacy relies on a combination of general competency with software and technologies, together with the ability to undertake more independent (especially informal) learning of discipline-specific knowledge as and when required. This conceptual framework is a response to current digital literacy and information literacy frameworks and related terms which do not go far enough to identify the implications of the choice of software applications and platforms on what can be achieved (Hegarty et al., 2010; Livingstone et al., 2013). The software literacy framework outlined here is intended to complement existing research on digital and information literacy; to more properly acknowledge the emergence of software as a cultural artefact possessing agency within social, cultural, economic and political practices (Fuller, 2008; Johnson, 1997; Manovich, 2013).

SOLUTIONS AND RECOMMENDATIONS

The potential of the three-tier software literacy framework was evidenced through a case study of university context teaching and learning environment. The aim was to explore, examine, and theorize on how the notion of software literacy is understood, developed, and applied in university teaching and learning contexts, and the extent to which this understanding is useful when translated into new contexts of learning with and through software (Khoo, Hight, Torrens, & Cowie, 2013). To address this broader aim, the study, confined to the disciplines of media studies and engineering, sought to explore the nature of informal and formal learning of software applications as an entry point in investigating the nature of software literacies fostered within distinct tertiary student cohorts. The study initially focused on student learning of PowerPoint as a generic form of software application, typically learned partially or wholly through

informal learning, before progressing to examining student learning of disciplinary-specific software learning in media studies (e.g. Adobe Photoshop, Final Cut Pro), and engineering (SolidWorks). Within both these disciplines, PowerPoint was a common feature of lecture sessions, but not specifically examined as software. While engineering students were required to learn SolidWorks (a 3-D design application) as part of disciplinary knowledge, the media studies students encountered software as part of production electives within a broader degree programme and were encouraged to use a range of applications as needed for creative projects. Each of these disciplines required students to apply professional-level creative and editing applications toward learning tasks, and provided detailed instruction in software which was both comparatively complex and relatively unknown to incoming student cohorts. Each disciplinary context also provided distinct sets of knowledge about software provided to students, contrasting experience with a range of alternative applications to those taught in workshops, but nevertheless shared expectations of the need for students to employ informal learning to complete their understanding of specific pieces of software. The overall objective was to understand the impact of more direct instruction (of sophisticated software applications) on student software literacy development and disciplinary understanding.

The findings of this study support the existence of the three-tier software literacy framework but indicate there is some flexibility in student development and movement between the tiers. It was demonstrated that student ability to achieve the higher tiers of software literacy did not preclude them from needing to revisit earlier levels in contexts where they encounter new but similar software. This suggests lecturers should not assume student competency with software across contexts (e.g., informal to formal, from campus to workplace settings). The framework provides a key conceptual tool for practitioners in terms of understanding the role of troubleshooting, for

example, as an important development stage in learning with and through software.

There was evidence of students having arrived at tier 3 (critical literacy) as well as those not moving beyond tier 2 (troubleshooting). For example, student (mis)assumption that the course lecture notes presented in PowerPoint's bullet point format in and of themselves constitute an adequate elaboration of pertinent disciplinary knowledge. The affordances and constraints that PowerPoint and discipline-based software offer in shaping disciplinary knowledge needs further consideration by students and by lecturers. Lecturers therefore need to be aware of the implications of their choice and modelling of a software application or platform. Findings suggest they would be wise to introduce and help students to develop critical awareness of how such software can inform and shape their own understanding of disciplinary knowledge and practice.

These findings were manifested in distinct but closely aligned patterns within each disciplinary context. However, there was also a difference in the way each discipline prioritized software literacy development as part of their student learning pathway and graduate profiles. For example, in the media studies case, critical thinking as emphasized in the third tier is seen as a core aspect of creative disciplinary knowledge. Being able to judge the creative capacities of competing software has implications for the nature of the practice which is being developed, the form and eventual conceptual complexity of media products themselves, as well as more practical considerations such as budget. In contrast, in the engineering case, students are expected to develop digital and software literacy skills as part of their professional learning. For graduates, the quality of engineering design produced and a design's efficiency and effectiveness are prioritized over the kinds of creative reflexivity observed in the media studies case study. Such disciplinary differences reveal a need for each discipline to continually reflect upon how discipline-specific software teaching and learn-

ing is positioned in relation to graduate profiles and the breadth and depth of literacies required to engage successfully with software.

Another clear finding reiterates that multiple learning pathways exist for exploring the affordances of any particular software, both formal and informal. Students tend to prefer informal strategies as a supplementary to and at times above formal strategies to learn discipline-based software (these included YouTube video tutorials, along with peer networks). Lecturers could usefully be informed by and take advantage of students' informal repertoire of learning strategies and networks including their accessing of (web-based) resources and pooling of peer expertise. Lecturers drawing from students' already established informal learning strategies would recognize the relevance of the social and cultural context in shaping effective technology and software engagement.

The findings importantly challenge current notions and assumptions of the digitally literate generation. When learning to use PowerPoint most students perceived themselves to be competent and confident early adopters of technologies and could identify the general affordances of generic software (PowerPoint) to the extent of critiquing the design and performance of PowerPoint practice in their lectures. They were able to recognize discipline-specific affordances among the applications formally taught and acknowledged these to be central in their engagement with disciplinary knowledge. However, very few were able to critique how the design of the *software* itself might shape their disciplinary knowledge. Very few students demonstrated critical thinking about the nature and role of the software they were using and most were not able to describe or discuss applications beyond those used in their learning. That is, there was very little evidence of tier 3 software literacy. Students' superficial critique of software challenges current assumptions that today's students as 'digital natives' have developed critical awareness simply through familiarity with and regular use of a variety of everyday applications and platforms. To reiterate, lecturers need

to explicitly teach and model software critique if they wish to foster this capacity and/or make this possibility known to students.

The diversity of student cohorts and the range of understandings and the variation in familiarity, skills and experience students bring with them to the formal software learning context constitute a further challenge for teaching of, through and about software. Some students may already have a critical orientation towards software (or, more frequently, toward specific applications). And there is demonstrably an advantage in terms of more advanced software learning for those who have prior experience with other software with a similar conceptual framework. In response to this diversity lecturers could usefully direct time and attention to formatively assessing students' initial software literacy and adapting teaching activities in light of this. Most crucially, however, the overall findings indicate there is no single best approach (one size fits all) to teaching discipline-specific software. Lecturers adopting a range of teaching approaches (formal and informal) and being flexible to address diverse learning needs represents a crucial part of supporting student learning.

FUTURE RESEARCH DIRECTIONS

Software is a site of cultural production and an actor in social, economic, political practices; it needs to be analyzed in terms of its embedded values and effects on such practices. The brief summary of case study findings outlined above is limited due to the situated nature of the investigation into discipline-specific software teaching and learning. The participants in the study represent a convenience purposive sample of lecturers and students from one educational institutional setting. They were from two distinctly different disciplinary contexts, with distinct and different disciplinary foci and expectations of software teaching and learning. Lecturers were also careful to point out the study only focused on some courses within a program and all universities have different inter-

pretations of how software teaching and learning can be enacted. Many educational practices are now intimately associated with software-based tools and applications, suggesting an urgent need for research which explores the implications for such practices and the manner in which they operate and are embedded within specific institutional, disciplinary and specific learning contexts. The software literacy framework outlined above offers a basis for addressing the social and cultural dimensions of software-centered learning, including the interactions between formal tertiary environments and informal learning networks.

CONCLUSION

Software literacy is an essential part of learning and living in the 21st century; something which transcends the use of any particular tool and any particular educational, social and cultural context. Software is an increasingly central part of the palette of understandings and skills which comprise the broadening umbrella of digital literacy. As a cultural artefact, software plays a role in reproducing, reinforcing, and augmenting existing cultural practices, as well as generating new practices. Software such as Google, the iOS software in iPhones and iPads, and Microsoft Office software packages are common examples reflecting the extent to which software has become embedded in everyday personal and professional pursuits. The reliance locally and internationally on algorithmically-centered big data for policy and funding decisions is another example of how software tools can influence the way we live. It is therefore desirable and advantageous that graduates (and other learners) have a critical understanding of software to make more informed choices about their use, can transfer this critical understanding to software they have yet to encounter, and understand that all software has nuanced affordances and limitations. This has implications for education providers, especially universities, in their role in fostering critical thinking and serving

as critic and conscience of society. It is crucial to ensure all students and lecturers are supported in teaching and learning processes when these are mediated through and focused on software. As society moves to exploit the potential of e-learning platforms, and make use of social media and cloud-based and mobile applications, there is a need for further detailed empirical investigation of software literacy. In tertiary settings, this is needed to ensure equitable and critical learning with, through and about software.

KEY TERMS AND DEFINITIONS

Affordance: A person's perceived opportunity to utilise a particular tool for action, for example, a doorknob is for turning. Within software, these are typically organised through user interfaces.

Media and Information Literacy: An umbrella term for a number of competencies, skills

and understandings associated with contemporary communication and information practices. This term encompasses the more specific term digital literacy, which is associated with digital media practices.

Pedagogy: Study and practice of teaching.

Software: Machine readable Instructions which directs a computer's processor to perform specific operations. For everyday software applications, these instructions are put into operation as computer users run an application.

Software Application: A computer program designed to perform a set of tasks or functions. Common everyday examples range from an 'app' on a smartphone, to desktop computer programs such as a web browser.

Software Literacy: A person's expertise in understanding, applying, problem solving and critiquing software in pursuit of particular learning and professional goals.

Software Platform: A coherent programming environment or system which supports applications. Examples include operating systems such as iOS or Android, or social media platforms such as Facebook.

Software Process Improvement for Web-Based Projects Comparative View

S**Thamer Al-Rousan***Isra University, Pakistan*

INTRODUCTION

In the last two decades, there have been a significant increase on the expectations and demand of Web-based application due to the influence of the World Wide Web on our modern economy (Pressman, 2004). At the same time, the development, deployment and maintenance processes of the web-based systems which have become more and more complex and difficult to manage, have not progressed at a sufficient rate to meet these demand and expectations (Cardoso, 2007).

Many developers of web-based projects do not take into concern the unique requirements and characteristics of Web applications. They fail to realize that characteristics and requirements of web-based systems considerably different from that of traditional software, and so does their development (Alrifai, 2008). Hence, many developers conduct web applications in an ad hoc manner, and fail to adopt sound design methodologies, resulting in poor quality web systems and applications. A survey by the Cutter Consortium (2006) shows that failure to meet business needs (84%), project schedule delays (79%), and budget overruns (63%), lack of functionality (53%) and poor quality of deliverables (52%) are the main problems cited by the stakeholders of such applications.

In finding solutions to the problems of web-based application development, there has been an increasing pressure on the Web-based application industry. The search for solutions to improve Web-based software development has continued for many years and Web-based applications organizations are now realizing that one of their

fundamental problems is the inability to effectively manage the Web-based applications development process (Sulayman & Mendes, 2011). Software Process Improvement (SPI) has been recognized as an efficient and effective way for organizations to improve their quality of the software they develop and the productivity with which they work with. For this, SPI is an essential tool for improving Web-based applications development process (Sulayman & Mendes, 2011).

Process improvement in Web-based software projects is of growing concern for many reasons such as reducing cost and time, producing high quality software, and improving productivity (Smite et al., 2011). Despite the importance of SPI implementation, there is evidence that the vast majority of Web-based software development organizations are reluctant to adapt SPI models and standard because of their complexity (Abdel-Hamid & Abdel-Kader, 2011). It has been detected that improvement efforts in Web-based software projects based on process improvement frameworks which are designed for traditional software projects fails most of the time (Sulayman & Mendes, 2011).

In the absence of theoretical or empirical work examining the suitability of the traditional SPI standards and models for Web-based projects development, we believe that it is important to examine the suitability of the existing SPI standards and models for Web-based projects development process. The motivation for this study was to fill the gaps in the field of software process improvement. The main contributions of this study are:

1. Examine the suitability of the existing software process improvement models and standards for Web-based projects.
2. Increasing awareness on the importance of software process improvement in Web-based projects.

We believe that achieving these goals will lead to enrich the SPI in Web-based projects with new properties that leads to enhance the SPI projects implementation.

BACKGROUND ON WEB-BASED SOFTWARE DEVELOPMENT

There is a relatively small but a rising research on the differences between the Web-based applications and traditional software development. In general, this literature shows that the Web-based applications have certain unique inherent characteristics that make Web-based development considerably different and possibly more difficult comparing with software development (Rousan et al., 2014). The Web-based application characteristics which are usually built in shorter time-frames, serving as direct interface to various stakeholders, should meet a broad set of requirements and more than often serve a specific group of users. They are usually built from template solutions, by using coarse-grained authoring tools, which were developed by a multidisciplinary team (Ginige, 2002). These characteristics constitute the reasons why many concepts, methods, techniques, and tools of traditional software development are either insufficient to meet the needs of Web-based applications or have to be modified in order to do so (Pressman, 2004). Thus, Web-based project developers must have a reasonable understanding of the characteristics of Web-based project development and how these may affect the outcome of the project.

Web-based project development process is a complex and a demanding activity. Hence, the development of high-quality Web applications

does not occur naturally, there must be a systematic plan, complete with managing and improving the process, testing, and evaluation, to develop and implement the Web-based software project accordingly (Smite et al., 2011). Under such demanding circumstances, SPI is becoming increasingly important for Web-based software project.

RELATED WORKS AND RATIONALE OF SPI

The motivation for execution process improvement activities is to gather information as to what needs to be changed and to set up how to follow the improvements in order to reduce development cost and increase the quality of products created (Pino et al, 2008). SPI is about making things better. Unfortunately, the majority of Web-based software development organizations don't concentrate on process improvement activities. Some cases about the implementation of SPI founded in literature. A case study about the performance of SPI models in Web-based software development was proposed in (Sulayman & Mendes, 2011). Software process improvement in Web-based software development based on agile methods was proposed in (Abdel-Hamid & Abdel-Kader, 2011). The continuous improvement in the basis of the existing method was been provided by Nawazish et al. (2010). It gives some comments and suggestions that must be followed during the Web-based software development process. It concentrates on the gathering information that need to be changed, reducing the cost of development, and increasing the quality of the product produced by setting up how to follow the improvements. Salinas et al. (2012) analyze whether the practices proposed in Scrum meeting the CMMI generic and specific goals or not. They found that the CMMI is not appropriate for Web-based projects that based on scrum.

Software process Improvement is a continuing practice and must always be followed up with the analysis of actual areas of improvement. When SPI implemented effectively, the results can be

measured in the enhancement of product quality, and customer satisfaction. The study by Nawazish et al (2010) gave a description of the strengths and weakness of SPI in terms of Quality Functional Deployment (QFD). It based on the customer satisfaction. It considers the customer's needs according to the CMMI model. Several SPI models are designed particularly to improve product quality and meet customer satisfaction. One of these models is OWPL model (Alexandre et al, 2010). OWPL model is employed to enhance the product quality and to evaluate process improvement on organizational development.

Many SPI models are technically challenging (Sulayman & Mendes, 2011). A lot of organizations undergoing SPI projects have reported encountering problems and difficulties. The study of Amescua et al. (2006) shows a list of the resistance factors that affects organizations that implement the SPI projects. Hall et al. (2002) stated some major problems encountered during the implementation of SPI project. However, these problems include: hardly transferred technology, poorly managed information, changeable goals, unclear picture about the current status of the SPI project, and unclear distribution of roles. In addition, Baddoo et al. (2007) stated that the deciding factor in minimizing project failure is effective communication among developers, users, and project managers.

Despite the importance of SPI, it regularly is seen as unnecessary bureaucracy between software engineers and computer programmers. Some of the SPI models are small and cheap, but they have amazing results in spite of their cost. Some take years and millions of dollars to apply in spite of their popularity. However, SPI models share some common characteristics regardless of their scope, size, and complexity (Falessi et al, 2014). In next section, we attempted to check the suitability of the some of the software process improvement models and standards to meet the special characteristics and requirements for the Web-based projects.

ANALYSIS OF THE RESISTANCE FACTORS IN WEB-BASED PROJECTS

Based on software process improvement (SPI) literature, there are various factors which are influencing the implementation of SPI project. This study has categorized all those factors according to Beecham's research as presented by Clarke & Connor (2012). All those factors have been broadly divided into 2 main categories which are:

1. Organizational factors and
2. Project factors.

The organizational factors related to problems within the scope of the organization and are usually under senior manager's responsibility as reported in (Ali & kalmsteiner, 2014), meanwhile project factors related to problems regarding the software project management such as planning, activities, resources among others.

- **Organizational Factors:** Software processes play an important role in coordinating different teams in large or small. These are the factors which are related within the scope of the organization and are usually under senior managers' responsibility as presented by Clarke & Connor (2012) and others as stated in (Johansen, et al., 2016; Laporte, et al., 2016; Aydan, et al., 2015; Laporte, & Chevalier, 2015; Laporte, & Connor, 2015; Galvan, et al., 2015; Garcia, et al., 2015; ISO/IEC, 2015; Clarke & Connor, 2015; Exter, 2014; Laporte, et al., 2014; Jeners, et al., 2013). There are 5 factors which are categorized under organizational factors namely: Human, Political, Cultural, Goals and Change Management. Table 1 provides a description states the key resistance factor for each one identified.

Table 1. Description of each organizational factor

Factors	Description	Key Resistance Factors
Human	Without commitment from all organizational levels (human) to support SPI, the initiative will most likely fail or the results are not far reaching (Clarke & Connor, 2015). The experience of senior management with an SPI project will give positive impacts to the improvement process. Consultation support such as advice and training of SPI action teams and staffs is one critical aspect in ensuring the success of SPI project (Laporte, et al., 2014).	• Lack of commitment in all levels of the organizations. • Lack of adhesion and participation of all the individual involved in SPI projects. • Lack of professionals experience and skill. • Lack of leadership and backup by top management level. • Lack of adequate training
Political	The political factor is important to the construction for a department to SQA (Garcia, et al., 2015). The establishment of quality policy which is one of the political issues comes after the commitment of senior management. Quality policies and standards for SPI efforts describe the organizational goals and objectives related to the quality.	• Lack of the establishment of organizational policies. • Lack of the establishment of Quality Policy.
Cultural	In order to ensure success in a cultural change program, a champion who can build, deploy, drive, and own each initiative going forward must be properly decided (Larrucea, et al., 2016). However, every cultural change program requires good cooperation from both management and tactical technical staff, improvement programs will fail if either group is left out or underemphasized	• Lack of expertise in implementing cultural changes.
Goals	According to Exter (2014) research, if the goals, deadlines, and expected results by the managers are impractical, the effort towards SPI may be unsuccessful Laporte, & Connor (2015) found a reason why software process needs to have indefinitely ongoing processes. It is essential that clear goals need to be specified earlier, so that progress towards those goals can be continually monitored, and so that revisions to either goals, of processes, or both can be made persistently.	• Lack of consistency between software processes improvement project and the organization's strategic objectives. • Absence of focus on the organization's most urgent needs. • Unrealistic expectation towards the SPI project.
Change Management	Initial analysis needs to be conducted to determine whether the SPI initiative apt with the organization' objectives and interests. This is also discussed and supported by Laporte, et al. (2016). Exter (2014) in conceived that the SPI project's team be used to actively facilitate the efforts toward changes on the part of the project teams rather than simply check the situation of the ongoing process in order to report a long and depressing list of findings. Clarke & Connor (2012) highlighted that in order to have a successful software process improvements, risk from configuration and change management which is not explicitly defined will lead to unsuccessful business process.	• Insufficient and ineffective assessment of the current software process

- **Project Factor:** These are the factor which reflects the resistance factors on ongoing project which contributes and gives impact during the software process and it involves contribution from all level of personnel management as described by Clarke & Connor (2012) and others (Exter, 2014; Laporte, et al., 2014; Jeners, et al., 2013). There are 4 factors which are categorized under project factors namely: Budget, Estimates, Documentation, Quality, Tools

and Technologies. Table 2 provides a description states the key resistance factor for each one identified.

SOFTWARE PROCESS IMPROVEMENT MODELS AND STANDARDS

Different software process improvement models and standards such as Trillium, BOOTSTRAP,

Table 2. Description of each Project factor

Factors	Description	Key Resistance Factors
Budget and Estimates	According to Laporte, et al. (2016) lack of progress in improvement plans is frustrating to those who really want to achieve progress and this put down the importance of time and costs in the process evaluation. Further research support by Aydan, et al. (2015) stated that the senior management often overlook on the manageability of SPI project size issue and sufficient budget size for SPI project issue. The first year is the most difficult period for a SPI program. Resistance to change will be at its peak, the costs are likely to be higher than in the 17 following years and due to the steep learning curve, the first year goals and targets can easily be missed.	• Current budget and estimates exceeds planning. • Lack of understanding by top management level that the software processes improvement project is a long-term return on investment process. • Lack of visibility about the ongoing software processes improvement project activities.
Documentation	In SPI project, documentation is a must in order to provide proof and dissemination throughout the organization in a formal way. Therefore, it is helpful to have an infrastructure for documentation, since it is a mandatory practice throughout the organization. According to Clarke & Connor (2012) the documentation is also gaining importance in the list of problems associated to SPI. It includes data measurement, proceedings register, coordination and management of the documentation, data collecting the operational framework forms the relationships and dependencies between what is to be done, by whom, and how to do it.	• Excessive documentation and formality. • Lack of infrastructure and of a documentation management. • Lack flexibility in the use of the documentation in projects of different types and sizes.
Quality	Quality refers to the state of the software as it was released or delivered to customers. In order to achieve higher level of quality assurance is by creating consent about how all the requirements definition processes has to be performed and which information should be provided to ensure the successfulness of the SPI project.	• Lack of involvement of top management in the relationship between the project teams and the person or group of quality assurance. • Lack of treatment to guarantee process conformity in instances of hiring and/or dismissal of skilled professionals.
Tools and Technology	The problem associated refers to the implementation of new tools and technologies, amount of work and pressures that hinder the use of new tools. According to Umarji, complexity of SPI tools and technologies need to ease with which developers can adapt to changes in work practices caused by SPI (Exter, 2014). However it has several acceptance issues because it often involves learning new technology, changes in work practices and an additional workload. Also, SPI involves collecting data about projects, resources and deliverables and often practitioners are not keen on sharing this type of data.	• Automation of not well-defined processes. • Lack of training on the support tools and technologies defined as support. • Pressure and absence of planning concerning the adaptation period.

SPICE, CMM, and CMMI have been proposed to help organizations to achieve more expectable results by improving their software process (Nawazish et al, 2010). This study discusses and compares some SPI models for Web-based project from a comparative view. The SPI models examined in this subsections all share common characteristics. They are well defined, measurable, repeatable, helpful, and widespread in use.

CAPABILITY MATURITY MODEL

The Capability Maturity Model (CMM) was developed by the US Department of Defense at Software Engineering Institute (SEI) in the mid-1980s (Salinas et al, 2012). CMM is used for the improvement of the existing software development processes, and can also be used to other processes. The main role of this model is

Figure 1. Capability maturity model

to develop a process maturity framework and to manage the process (Falessi et al, 2014). This framework supports the organization to enhance their software process by using the five maturity levels (Initial, Managed, Defined, Quantitatively Managed, and Optimized Levels) (Dangle et al, 2005). Figure 1 shows the CMM model. Each level in CMM needs to accomplish several Key Process Areas (KPA's) which composed of key practices that contributes to satisfying their aims and objectives.

Maturity levels consist of a predefined set of process areas. The maturity levels are measured by the achievement of the specific and generic goals that apply to each predefined set of process areas. Every Key Area must be implement the predefined objectives, which are, the essential infrastructure of the objective satisfaction or the activities to be developed. Every maturity level creates a different component in the software process, resulting in the capability increase of the organization process (Falessi et al, 2014).

For Web-based projects, this model is having certain disadvantages: First, When organizations use CMM, the developers look to the next level as

a target, this can be a risky for Web-based projects because if they become highly concentrated their attentions on reaching the next level, they may forget the actual target, namely to improve the processes. Second, CMM has sometimes been problematic. The application of multiple models which has not been integrated within an organization could make assessment, training, and improvement activities to be costly and take long time. The fact found in several empirical studies is that Web-based project is very short, usually not more than six months, and the average is less than three months (Al-Rousan et al, 2013). Finally, CMM approach would be very helpful when it is incorporated early enough in software development which mean it cannot be used to recover from a crisis in an emergency situation (Dangle et al, 2005). For Web-based projects the requirements of the target groups are unknown at the beginning of the project and project requirements change continuously, causing the vision of the Web-based application to evolve continuously which make the CMM approach unsuitable for Web-based projects development process.

CAPABILITY MATURITY MODEL INTEGRATION

Capability Maturity Model Integration (CMMI) was created by Software Engineering Institute by combining the CMM models (SW-CMM V2.0, Integrated Product Development (IPD), and System Engineering CMM (SE-CMM) (Salinas et al, 2012). CMMI focuses on a set of process areas that are related to software process improvement and capability. CMMI is the same as CMM, it shows the processes areas in five maturity levels. The difference can be seen from the fact that CMMI is an integrated approach that establishes a framework for the purpose of building an initial set of integrated models, or are used to integrate future and current models. CMMI has two representations (Jaramillo et al, 2015):

1. **Stages Model:** Designed to provide a standard sequence of improvements. It provides a way to assess the company's process capability at 1-5 levels (Initial, Aware, Defined, Quantitatively, and optimizing).
2. **Continuous Model:** Focus on the specific processes areas that are considered important for the company's direct business goals. Each process area is rated in terms of maturity level (0-5).

The main difference between the two representations is that the staged model is used to evaluate the capability of the company as a whole, while the continuous model is used to assess the maturity of certain process areas within the company.

CMMI includes a set of goals, which are brief descriptions of a wanted state that must be reached by a company. The CMMI has also specific goals, which are related to each process area and describe the wanted state for that area. In addition, CMMI includes a set of generic and specific practices that cover a set of process areas. These practices describe the ways of achieving a goals. Many generic and specific practices be related with every goal within a process area (Kerzazi, 2015).

Regardless how good CMMI approach can be; for Web-based projects, this approach is having certain disadvantages: First, CMMI has a lot of technical definition and documentation because it covers practically the whole thing from initial level process to optimized level, which make it ambiguity (Dangle et al, 2005). As the short development cycle is so common for Web-based projects, it is assumed to be the first requirement in the Web-based project improvement process (Pressman, 2004). Second, documentation is a must in order to provide proof and dissemination throughout the organization in a formal way. Therefore, it is helpful to have an infrastructure for documentation, since it is a mandatory practice throughout the organization. Thus, in order to initiate CMMI-based process improvement in Web-based projects, it requires a major shift in organizational culture and attitude, which make it hard and expensive.

Finally, CMMI approach just provides developers practices that are required to improve the process but it does not state how to implement them (Jaramillo et al, 2015). In addition, CMMI has a lot of technical definition and documentation because it covers practically the whole thing from initial level process to optimized level, which make it ambiguity (Dangle et al, 2005). With the high degree of individuality and multidisciplinary team in Web-based projects, the implementation of this approach in Web-based projects become fuzzy. As a result, this led to the argument that CMMI approach is not suitable for the development process of Web-based projects.

TRILLIUM

Trillium model was developed by Bell Canada, Nortel and Research Bell Northern. It combines requirements from the ISO 9000 series, CMM, internal Bellcore standards, and software quality standards from the IEEE (Harrington, 2011).

Trillium model and its application have been developed based on the feedback and experiences

of the suppliers (Model & Eizenman, 2012). It has been used for self-evaluation and for the evaluation of existing and possible suppliers. Trillium model was primarily designed for use with embedded software systems (for instance, telecommunications). So, Trillium model includes process info that is exclusive to the telecommunications field (Harrington, 2011). Nevertheless, much of the model can be useful to other parts of the software industry for example Management Information Systems (MIS). Although the Trillium model is based on the SEI model (CMM version 1.1), its structural design differs from the CMM in the following ways (Harrington, 2011):

1. Trillium model structural design is based on roadmaps, instead of key process areas present in CMM.
2. Trillium model has a wider product perspectives instead of only perspective that based on SPI.
3. Trillium has more awareness about issues that impacting on capability.
4. Trillium model has awareness towards customer concerns, telecommunication industry and technological maturity.

Trillium is comprised of five levels. These are (Gonzales et al, 2006):

1. **Unstructured:** The software development process is ad-hoc. Projects normally cannot meet schedule targets or quality. Success is based on individuals instead of organizational infrastructure.
2. **Repeatable and Project Oriented:** Individual project success is accomplished via stable project management planning and control, with emphasis on estimation techniques, requirements management, and configuration management.
3. **Defined and Process Oriented:** Processes are identified and used at the organizational level, though project customization is still

allowed. Processes are improved and controlled. ISO 9001 requirements such as internal process reviewing and training are integrated.

4. **Managed and Integrated:** Process analysis is used as a major mechanism for process improvement. Process change management and fault restriction programs are integrated into processes. CASE tools are integrated also into processes.
5. **Fully Integrated:** Formal methodologies are widely used. Development history and organizational repositories are used are integrated into processes. Every capability area span several levels.

Every level (except first level) includes numerous capability areas, which in turn cover roadmaps that included activities. These is very similar to CMM. Every capability area combines one or more roadmaps, and each roadmap includes one or more practices that span numerous Trillium levels (Harrington, 2011).

For Web-based project, this approach is having certain disadvantage: The model includes process information that is unique to the telecommunications field, and a significant percentage of the practices described in the model related directly to hardware development. For this, Web project cannot be adopted as-is. In addition, Formal methodologies, stable project management planning and control are critical for this model. In Web-based project, developers must deal with unknown field of businesses and the business requirements may change dramatically, so the formal methodologies are hard to be adopted. Furthermore, Trillium model need adequate training, professional experiences and skills, while Web application developers are significantly young, and they have less experience compared to the traditional software developers. Moreover, the time to learn and apply these kind of models is frequently not available which make the Trillium approach unsuitable for Web project development process

HEALTHCHECK

In 1982, Healthcheck was developed within the British Telecom (Mackie & Rigby, 1993). The goal was to find an approach of evaluating software process versus existing world best practice to allow direct improvement initiatives for software process, product and staff working in software development. The purpose was to improve the quality of the software and so to understand where to allocate investment in changes. The idea was to apply a series of face to face interviews with team members that work on a particular project or unit in order to assess them (Patricia, 2004). All interviews are based on the Healthcheck questionnaire, which consists of nine key process areas, each process area containing from 10 to 16 questions (Norris et al, 1994). Software development team members should be involved from the very start of the interview process, because their opinion counts when making decision on what needs improvement or adjustment. The key process area are scored on a percentage scale. Based on experts' view, the key process area with 100% score indicates that a unit is working according to existing world best practice. The results are showed as radar diagrams using a percentage scale (Patricia, 2004).

In Web-based, the major problems in starting SPI process is with managing the resources such as methods, practices, people, tools and technology they use. Besides, Web-based organizations are expanding their businesses with other client organizations. This is done in order to decrease cost and improve operations. Web-based organizations are employing more qualified and experienced people who are not part of their organizations or organizational process. So it's hard to take their opinion when making decision on what needs improvement or adjustment.

Healthcheck model idea was to apply an improvement cycle that included steps identified as assess, analyses, modify and execute. For Web-based projects, applying this cycle is a complex

job due to relatively short development time and the complexity of Web-based software development environment and the process. In addition, Healthcheck model needs participation of all the individual involved in SPI process. It also need commitment in all levels of the organizations. Boundaries between countries in Web-based project development are disappearing, and software development process is becoming globally oriented, multidiscipline and cross-cultural which make the practices adopted in Healthcheck unsuitable for Web-based projects development process.

SOFTWARE PROCESS IMPROVEMENT AND CAPABILITY DETERMINATION

Software Process Improvement and Capability Determination (SPICE) is an international framework for assessment of software processes. SPICE developed cooperatively by the IEC (International Electro technical Commission) and the ISO (International Organization for Standardization). SPICE is also known as ISO/IEC 15504 (Laporte et al, 2006).

SPICE was build based on existing software estimation models such Trillium, CMM, and Software Technology Diagnostic (STD) (Rout et al, 2007). SPICE provides a group of documents, which are worked as a framework for the measurement of software process. Organizations can employ these documents in numerous stages of production, for example in planning, managing, monitoring, controlling and improving acquisition, supply, development, operation, evolution and support of software (Rout et al, 2007).

The SPICE documents was accordingly structured into seven working groups trying to provide information to create a standard for software process evaluation and improvement. The working groups had specific goals for creating the seven products that were to include the SPICE product group. The products were (Rout, 2010):

1. **Introductory Guide (IG):** Shows how different parts of the standard fit together and offers guidance for their selection.
2. **Baseline Practices Guide (BPG):** Describes the goals and important activities that are essential for good software engineering, and more precisely defines what activities are needed but not how they are implemented.
3. **Assessment Instrument (AI):** A guide for designing tools that elicit data related to the processes undergoing estimation.
4. **Process Assessment Guide (PAG):** A document that identifies the estimation method, which in turn describes how to perform the estimation using the estimation tool and the basic practices.
5. **Process Improvement Guide (PIG):** Offers guidance on how to use the estimation outcomes for process improvement.
6. **Process Capability Determination Guide (PCDG):** Offers generic guidance on how to employ the estimation outcomes for capability evaluation.
7. **Assessor Training and Qualification Guide (ATQG):** Offers generic guidance for the development of programs intended to train staff as evaluators utilizing this standard, and procedures.

This approach has certain disadvantages for Web-based projects. First, the development of ISO/IEC 15504 was based on the weaknesses of previous standards and models. It is considered as to complement other international standards and models for assessing the capability, effectiveness and quality of processes and organizations, for this is not easy to be understood. Second, ISO/IEC 15504 was created in a development context, making it difficult to apply in a service management context. Third, the staff who will take part in SPICE initiative most have relevant education and training and experience, personal qualities such as communication skills, specific skills for particular groups such as management skills for

the management group, and ISO/IEC 15504 related training and experience in process capability assessments. As result, SPICE approach unsuitable for Web-based projects development process.

CONCLUSION

This study reviewed different software process models and techniques that are helpful in software process improvement. All SPI models and standards mentioned above are different in characteristics. There is no single SPI approach studied in this study, which is able to meet all the requirements and characteristics of Web-based project development. Considering the importance of Software Process Improvement, and as the Web-based development projects is still lacks of the SPI models and standards that could serve as a guideline to the development of Web-based applications, it is extremely important that Web-based application developers understand the strengths and weaknesses employed on existing SPI models and standards, and they should adopt and adapt the best SPI models and standards or coming with a new models and standards to meet the requirements and challenges of the Web-based application development.

FUTURE RESEARCH DIRECTIONS

Main objective of this study was to investigate specific SPI models or techniques for Web-based projects development. The review as mentioned earlier helped us in identifying the possible research gaps and directions. One of the research gaps lies in proposing a specific SPI model for Web-based projects, which keeps in view their characteristics and aims to help them measure their success and improve continuously. This can be achieved by either enhancing some existing SPI model or by proposing one from scratch. This is the line of our future work.

KEY TERMS AND DEFINITIONS

CMMI: A model that supports evaluating and improving an organization's processes using a best-practice model.

ISO/IEC: An international standard for evaluating and improving an organization's software processes.

Model: An abstract and simplifying representation of an object or phenomenon of the real world.

Model-Based on SPI: Model-based on SPI approaches compare the current processes and practices of a development organization against a reference model or a benchmark.

Process Improvement (SPI): SPI means understanding existing processes and changing

these processes to increase product quality and/or reduce costs and development time.

Process Model: Representation of a real-world process that focuses only on specific features of the real-world process and does not capture all details.

QIP: The Quality Improvement Paradigm (QIP) is a six-step procedure for structuring software development and improvement activities.

Software Process Model: A software process model is a model of a software process.

A Study of Contemporary System Performance Testing Framework

S**Alex Ng***Federation University, Australia***Shiping Chen***CSIRO Data61, Australia*

INTRODUCTION

System Performance Testing is a vital activity spanning the Software Development Life Cycle (Siva & Sharma, 2006). There are different types of test: Functionality, Graphics, Collision, Performance, Gaming, User Interface, Progression, Correlation, Numerical, Conformance, Interoperability and many more. In this chapter, we find special interest in System Performance Testing. The purpose of system performance testing is to identify bottlenecks by measuring a system's responsiveness and scalability under a certain load (Sarojadevi, 2011). Load testing provides a means for assessing the behavior of a system under varying traffic burdens. Performance testing is able to provide simulation and modeling help enterprises experiment not just with load but also with specific situations, such as large numbers of users performing the same activity conducting a search or completing an online transaction simultaneously (Menascé, 2002). Performance tests conducted over time provide a good landscape trend which helps companies plan and test for future needs. Such testing can help determine what hardware resources need to be purchased to achieve desired future capabilities (Jain, 1991).

In this chapter, we discuss some of the contemporary system performance testing frameworks and present a general-purpose testing framework for both simple and complicated performance testing. We observed that few of the system

performance testing frameworks available have been widely used in industry or the research community (Yigitbasi, Iosup, Epema, & Ostermann, 2009). Our framework proposes an abstraction to facilitate performance testing by separating the application logic from the common performance testing functionalities.

The rest of this chapter is organized as follows. We first provide a definition of system performance and the requirements for system performance testing framework. Afterward, we present a discussion of some of the contemporary system performance testing frameworks. Lastly, we propose a system performance framework with a sample implementation to demonstrate the applicability of this framework.

BACKGROUND

According to (Meier, Farre, Bansode, Barber, & Rea, 2007), Performance Testing is defined as the technical investigation done to determine or validate the speed, scalability, and/or stability characteristics of the product under test. Performance-related activities, such as testing and tuning, are concerned with achieving response times, throughput, and resource-utilization levels that meet the performance objectives for the application under test.

(Meier et al., 2007) classify performance metrics into the following categories:

- **Network-Specific Metrics:** A set of metrics about the overall behavior of the network used to support the system.
- **System-Related Metrics:** A set of metrics helps identify the resource utilization of the system.
- **Platform-Specific Metrics:** A set of metrics related to software that is used to host the application system, such as the Microsoft.NET Framework common language runtime (CLR) and ASP.NET-related metrics.
- **Application-Specific Metrics:** These include custom performance counters inserted into the application code to monitor application health and identify performance issues.
- **Service-Level Metrics:** A set of metrics help measure overall application throughput and latency, or they might be tied to specific business scenarios.
- **Business Metrics:** These metrics are indicators of business-related information, such as the number of orders placed in a given timeframe for a particular department.

There are some common system performance metrics for enterprise systems, such as: *Response Time*, *Latency*, and *Throughput*. In some contexts it's customary to call these things by different names: *Throughput and Response Time*, or *Capacity and Delay*, or *Bandwidth and Latency*. We provide the following definitions to avoid ambiguity:

- **Response Time (RT):** It is the total time taken by a client to wait in invoking a server function and coming back with a result. Oxford Dictionary defined RT as *the length of time taken for a person or system to react to a given stimulus or event*.
- **Latency:** It is the total time spent by a system generated message to travel from its source to the destination. According to Oxford Dictionary, "latent" means "exist-

ing but not yet developed or manifest". Together, latency and bandwidth define the speed and capacity of a network. For an online system, latency is the total time spent by a message from its sender (source) to its receiver (destination).

In a synchronous client/server-based environment, RT is equivalent to Latency, where the client is both the message sender (requester) and receiver (respondent). This is why these terms are sometimes used alternatively. However, they are different in the asynchronous mode because the sender and the receiver are two different parties. The total time spent by a client (RT) in invoking an asynchronous request and waiting for the result to come back will be different from the total time for a message (Latency) to get from the source to its destination because the message sender may be different from the message receiver.

Furthermore, there exists a term called *Processing Time* to describe the amount of time a system takes to process a given request, not including the time it takes the message to get from the user to the system or the time it takes to get from the system back to the user.

With this view, Latency + Processing Time = Response Time.

- **Throughput:** It represents the server's capability in handling a certain number of client requests (such as messages or transactions) within a unit of time (such as second or minute). This shows how well a company's facility is able to cope with the demand of its client.

From Figure 1, we can see the throughput of a typical system demonstrates the following conditions: (1) *Nominal Capacity*: maximum achievable throughput under ideal workload conditions. (2) *Usable capacity*: maximum throughput achievable without exceeding the pre-specified response-time limit, and (3) *Knee Capacity*: A condition that starts to deviate from the linear

Figure 1. Typical throughput of a system

relationship between throughput and load. The *knee* is arrived when the response time is low and with high throughput.

REQUIREMENTS FOR SYSTEM PERFORMANCE TESTING FRAMEWORK

(Jain, 2015) specified seven criteria for selecting and evaluation technique for system performance:

- **Stage:** Select the appropriate technique suitable at different development life-cycle stage.
- **Time Required:** Consider the time effort required to implement the particular technique.
- **Tools:** Select the tools that are readily available that suits the environment.
- **Accuracy:** Specify and design the level of accuracy required by the system.
- **Trade-Off Evaluation:** Make smart consideration on the trade-off of different criteria.
- **Cost:** Select a technique that is most cost effective.
- **Saleability:** Ensure the selected technique should be reusable in the future.

(Pressman, 1992) asserts that there are several common characteristics emerge when devising

metrics to measure system performance: *Simple and computable, Persuasive, Consistent and objective, Consistent in units or dimensions, Programming language independent and Gives feedback.*

According to (Mansharamani, 2011), the requirements for performance test consist of two groups: *understanding specifics of the workload*, and *gathering performance targets*. On the other hand, (Meier et al., 2007) stress that performance testing is conducted to address one or more risks related to *expense, opportunity costs, continuity, and/or corporate reputation*. Furthermore, (Illes, Herrmann, Paech, & Rückert, 2005) specify quality criteria for testing tools basing on the ISO/IEC 9126 standard (ISO/IEC, 2001) for software product quality: *Functionality, Reliability, Usability, Efficiency, Maintainability, Portability, General vendor qualifications, Vendor support, and Licensing and pricing*. In addition, (SOASTA, 2014) stresses that the top ten performance problems are related to issues with: *Architecture, Bandwidth, Load Balancer, Third Party Services, Connectivity, Shared Environment, Database Performance, Configuration Settings, Application, and Culture & Mindset*.

Figure 2 is a summary of the requirements for a system performance testing framework in three different categories: Design and Operation requirements; Identification of performance problems and/or patterns requirements; and Metrics requirements.

Figure 2. Requirements for system performance testing framework

AN OVERVIEW OF CONTEMPORARY SYSTEM PERFORMANCE TESTING FRAMEWORKS

System testing is a costly and time-consuming activity in software development (Rankin, 2002). As a result, a large number of automatic performance testing products and open source tools have been developed to address the above requirements, such as IBM's Rational Performance Tester and Rational Test Workbench, HP's LoadRunner ("HP loadRunner," 2015), Microsoft's Web Application Stress Tool ("Microsoft visual studio testing tools," 2015), Apache Jakarta's JMeter ("Apache jmeter," 2015), and Grinder ("The grinder, a Java load testing framework," 2015). Moreover, there are other products such as CA Technologies Service Virtualisation, HP Performance Centre, and Neotys Neoload ("Performance testing products," 2015).

Recent advances have enabled analysis tools more dynamic interaction with the application under study. The new trends of development in social computing, mobile services, information

explosion, and cloud computing has enabled many visionary elements being evolved rapidly and are fragmented. While these performance products and tools have been successfully used in a range of enterprise applications, few of them have been widely used in industry or the research community, partially due to the fact that they are either too expensive and complicated for small projects and companies, or too specific and simple for testing a wide variety of applications.

The Garner Magic Quadrant for Integrated Software Quality Suites report (Driver et al., 2014) named IBM, Microsoft, HP, Oracle, SOASTA, and Borland are among the Leaders Quadrant in the Integrated Quality Assurance (IQA) tool suite market. This development indicates not only the importance of performance testing, but also the attraction and popularity of these kinds of product. The leader products are generally supporting a broad set of technologies encompassing aspects such as integration, connectivity, synchronization between the suite components and other tools within the software development life cycle.

Table 1. Overview of contemporary system performance frameworks

Vendor: Product Name	Complete Test Management	Load Test Automaton	Support Mobile, Web and Legacy Applications	Versatile Reporting	Persuasive Metric	Ease of Installation and Setup	Cost / License
Borland: Silk Performer	Yes	Yes	Yes	Yes	Yes	Yes	Medium
CA Technologies: Service Virtualization	Yes	Yes	No	Yes	Yes	Medium	Medium
HP: LoadRunner and Performance Centre	Yes	Yes	Yes – Strong for Windows	Yes	Yes	Difficult	High
IBM: Rational Performance Tester & Rational Test Workbench	Yes	Yes	Yes	Yes	Yes	Medium	High
Microsoft: Application Centre Test	Yes	Yes	Yes	Yes	Yes	Yes	Medium
Oracle: Application Test Suite	Yes	Yes	Yes – Strong for database	Yes	Yes	Medium	Medium
SOASTA: SOASTA Platform	No	Yes	No – Focus strongly at cloud & mobile load testing for Web applications	Yes	Yes	Medium	Medium
Open Source: JMeter / Grinder	No	Yes	No – Java based Web Application only	No	Medium	Medium	Nil

Each framework has unique things that it does and conversely, each of the tools have unique deficiencies that will impede the effectiveness of individual test plan.

We assert that there is no one particular system performance testing framework that fits all – any option selected will be something of a trade-off. All the leaders provide friendly user interfaces, powerful automated script generators, and comprehensive performance analysis and reporting features. However, most of these functionalities are for web applications.

In particular, these products are considered very expensive and the prices are usually binding to the number of concurrent loads. For example, one of the leader products can cost around US\$65K

for a license with 100 concurrent clients. This makes it difficult to use the products for small companies and budget-hardship projects.

The Table 1 provides an overview of the features demonstrated by some of the contemporary system performance frameworks.

Apache Jakarta's JMeter ("Apache jmeter," 2015), and Grinder ("The grinder, a Java load testing framework," 2015) are two open source performance testing tools for the Java environment. The Grinder load testing framework can run a distributed test using many load injector machines. It can load test any Java APIs including HTTP web servers, SOAP and REST web services, and application servers (CORBA, RMI, JMS, EJBs), as well as custom protocols.

The Apache JMeter offers test functions including: Web - HTTP, HTTPS, SOAP / REST, FTP, Database via JDBC, LDAP, Message-oriented middleware (MOM) via JMS, Mail - SMTP(S), POP3(S) and IMAP(S), MongoDB (NoSQL), Native commands or shell scripts, and TCP. JMeter has no monitoring built in. Therefore, the user is required to program wrapper scripts to synchronize test data with external performance monitoring data.

A GENERAL-PURPOSE SYSTEM TESTING FRAMEWORK

(Kelly, 2003) has highlighted five types of test automation frameworks which were commonly employed:

- **Test Script Modularity Framework:** Small, independent scripts are run in a hierarchical fashion to construct larger tests, realizing a particular test case.
- **Test Library Architecture Framework:** This technique is to divide the application-under-test into procedures and functions library files (e.g APIs, DLLs) that represents modules, sections, and functions of

the application-under-test. These library files are then called directly from the test case script.

- **Keyword-Driven or Table-Driven Testing Framework:** The type of framework develops data tables and keywords, which are independent of the test automation tool, to execute them and the test script code that “drives” the application-under-test and the data. In a keyword-driven test, the functionality of the application-under-test is documented in a table as well as in step-by-step instructions for each test.
- **Data-Driven Testing Framework:** In this type of framework, test input and output values are read from data files (such as, datapools or cvs files) and are loaded into variables in captured or manually coded scripts. Variables are used for both input values and output verification values. Navigation through the program, reading of the data files, and logging of test status and information are all coded in the test script.
- **Hybrid Test Automation Framework:** This is the most commonly implemented framework utilizing a combination of all of the above techniques.

Figure 3. A general purpose performance testing framework

We are now going to introduce a general-purpose system testing framework developed by us. An abstraction of our framework is shown in Figure 3.

This framework consists of three entities, (1) configuration and scripts, (2) test driver and (3) test results. They are interacted in the following manner:

- The test driver requires one or more configurations and scripts as inputs. The configuration file is used to control the setup of the test environment, specifying parameters such as the number of client threads to be used, the duration of the test run, and the payload types. The script is used to specify how to run a test in either product-specific languages (Rational RobotJ) or general-purpose languages (C/C++, Java, Perl, Python, Ruby etc.);
- According to the inputs, the test driver creates a specified amount of loads (threads and processes) to simulate concurrent clients or requests to stress the tested application, such as a web server. The target application under test will receive the test

request messages, performs the request and returns the result to the test driver.

- After all the threads and process finish their testing, the test driver will collect individual test results and combine these results into a final (usually summarized) test report.

ARCHITECTURE FOR SINGLE PROCESS/MACHINE PERFORMANCE TEST

Based on the above descriptions, we developed a general-purpose performance testing framework for single process performance tests. Figure 4 shows the overall architecture and its basic components and interfaces.

This framework uses a common interface, called *IRunner*, to separate the application logics from the other components. The interface captures the common requirements for testing a variety of applications/technologies, described as follows:

- ***init(app)***: Each thread may need to make preparations by calling *init()* before a test,

Figure 4. Overall architecture of a general-purpose system performance testing framework

to perform actions such as setting up a connection to the server, initialize test data, and clean and populate databases. The argument (app) is a set of application specific properties input by the tester. *init()* is run only once for each test.

- **run():** This method is repeatedly called by each thread during testing to complete a specific business operation, such as invoking a web service function, updating database, etc. This interface gives full control and flexibility to the tester to define and program what to test and how to test.
- **preRun()/postRun():** These methods are called, respectively, to make preparations and/or clean-up before/after each test iteration, i.e. each invocation of the above *run()*. They can also be used to simulate application behaviors, such as thinking and typing time by sleeping for a certain time.
- **done():** This method is called after the completion of all test runs to release some resources (connection to DB/web server) and to export the local summary results to the global results. This method is exclusively executed to ensure the consistency of the global results. Both Java and .NET have native support of the exclusive execution by marking the method as ‘synchronous’.

To test a specific application, the test engineer simply implements all or some of the above interfaces by programming the specific application logic in the corresponding language. This makes the framework capable of testing a wide variety of technologies and applications. Figure 4 illustrates two implementations of *IRunner* (*Tester1* and *Tester2*) to test two different applications, i.e. Application 1 and Application 2. The C# code shown in Box 1 is incomplete which shows the skeleton of each client thread’s run method only.

Another architectural decision of our testing framework is to support two user interfaces, i.e. Graphics User Interface (GUI) and Command

Box 1.

```
public void run()
{
    // instance the common interface IRunner
    IRunner runner = ...
    // before test: prepare test
    runner.init(this.config);
    // during test
    for(alarm.start(); !alarm.isTime(); numTx++) {
        runner.preRun();
        timer.start();
        runner.run(); // To run one iteration of your test
        latency = timer.stop();
        if(alarm.isTesting()) localLog.add(latency);
        runner.postRun();
    }
    // after test: add the local log to the global log
    runner.done();
}
```

Line (CMD), as shown in Figure 4. As a result, a uniform configuration is designed to be shared by the two user interfaces.

Single Uniform Configuration

Our system uses a single XML file for all configuration parameters of each test, including the general testing parameters (such as number of concurrent clients, running time and result logging file names) and application-specific data. This will simplify the testing configuration management effort. We carefully defined a flexible configuration schema in order to cover most test cases in terms of different applications and technologies. Figure 5 presents an overview of the schema (data model). Our configuration data model has the following features:

- Support for multiple catalogs that can be used to group a set of parameters (properties) for a certain purpose.
- Support any number of properties of each catalog for extension.
- Instead of defining strong schema tag names, we only define a structure of the configuration data model and then pre-define a set of properties ‘keywords’ used for

Figure 5. Schema of the 'universal' configuration

a specific version of the framework implementations. This makes the configuration always extendable without the need for frequently changing the XML schema code.

Box 2 shows an example of testing configuration based on the above schema.

In Box 2, all the property names in the catalog named 'Control' (type='test') are predefined as reserved keywords for all performance tests. These

property values are used by the common test driver to conduct general-purpose performance test tasks, such as how many concurrent thread required to create, how long each thread to run, etc. The C# code in Box 3 shows how the test driver use the parameter 'numClients' to generate the corresponding amount of concurrent threads.

On the other hand, the catalog named 'TPCC' (type='app') can contain any properties used by a specific application, such as TPCC in this case.

Box 2.

```
<Config name="Test1" note="TPCC testing">
  <Catalog name="control" type="test">
    <Property name="numClients" value="100" />
    <Property name="testTime" value="80" note="sec" />
    <Property name="warmup" value="0.1"
      note="10% of testTime" />
    <Property name="cooldown" value="0.1"
      note="10% of testTime" />
  </Catalog>
  <Catalog name="TPCC" type="app">
    <Property name="dbString" value="....." />
    <Property name="numWare" value="10" />
  </Catalog>
</Config>
```

Box 3.

```
public void test()
{
  // create and start multiple threads/clients
  Thread[] client = new Thread[numClients];
  for(int i=0; i<numClients; i++) {
    client[i] = new Thread(new ThreadStart(this.run));
    client[i].Start();
  }
  // To wait all threads to finish
  for(int i=0; i<numClients; i++) client[i].Join();
}
```

Architecture for Distributed Testing

To support large-scale load testing for enterprise systems, multiple testing machines must be used to generate a large amount of concurrent requests to stress enterprise applications. Our framework provides a reference architecture for distributed performance testing by leveraging the above single process testing architecture via loosely coupling messages as shown in Figure 6.

An explanation of the architecture for distributed testing environment is provided as follows:

- The above described single test driver is deployed and run on each testing machine, i.e. Tester 1, Tester 2, ... Tester N.
- The configuration used for running the test instructs the driver to receive further test control information from the Test Manager by subscribing the same or different specific topics (or messaging queue) depending on the Tester's role.
- The Test Manager will control these test drivers by sending the corresponding topic

or queue configuration XML via the enterprise bus.

- The Testers who subscribes to the topic will receive the configuration XML and start a test run according to the configuration in exactly the same way as single process/machine testing described in the previous section.
- After the test run, each test driver will send its test report to a topic (message queue) as specified in the configuration file.

Our framework provides a number of test harness designs to support the common functionalities of performance testing:

- **Configuration:** This component hosts all configuration data;
- **Alarm:** This component controls the whole test, such as when the test completes and if to log the test results;
- **High-Resolution Timer:** This component measures the latency and response time with higher resolution (3.27E-07 msec on Windows);

Figure 6. The architecture of a distributed general-purpose system performance testing framework

Box 4.

```

public class ResultLog
{
    // private members
    string name;
    int counter; // Num. of samples
    double sumValue; // Sum of sample values
    double maxValue = 0.0;
    double minValue = 999999999.9;
    int[] valueDistribution;
    .....

    // public methods
    public void add (double sample); // add a sample
    public void add (ResultLog log); // add another log
    public double getAverage (); // return the mean
    public double getMax (); // return maxValue
    public double getMin (); // return minValue
    ...
}

```

- **Random Generator:** It will generate random testing data (number and string) at runtime;
- **Result Log:** This component hosts all test results for one measurement.

For illustration purpose, we provide the design for the **ResultLog** as follows in C# in Box 4.

The C# code in Box 4 shows the result log includes all the performance metrics defined in previous section. Note that instead of hosting the average directly, the log contains only the sum of each measurement and the total number of sampling so that it can derive the mean (average) of the measurement using one after test. To log the distribution of each measurement, we use an array of integers (*valueDistribution*) to host the numbers of samplings fallen into individual elements of *valueDistribution* with the code shown in Box 5.

This framework has been implemented on both Java and .NET platforms. These implementations have been validated by a number of academic research projects; able to support a variety of large-scale performance tests via the extendable configuration (Chen, Ng, & Greenfield, 2013; Chen, Yan, Zic, Liu, & Ng, 2006; Ng, 2007; Ng, Chen, & Greenfield, 2004; Yao et al., 2012).

Box 5.

```

public void add(double value)
{
    sumValue += value;
    counter++;
    if(value > maxValue) maxValue = value;
    if(value < minValue) minValue = value;
    int index = (int)(value/disUnit);
    valueDistribution[index]++;
}

```

disUnit is the unit value (scale) for the element (bucket) of *valueDistribution*.

FUTURE RESEARCH DIRECTIONS

Recently, we have seen the shift from the traditional focus in the application quality management (i.e. load/stress and functional/regression testing) towards greater emphasis on productivity (i.e. agile development such as the Scrum framework (www.scrumalliance.org)) to improve time to market. Apart from that, packages, SaaS and business process management are driving greater business analyst involvement in overall quality efforts, along with a shift in focus from finding defects in validation to meeting business objectives.

In summary, we consider the following four areas are the major driving forces in shaping the development of future system performance testing frameworks:

- **Cloud:** The cloud has already reshaped the load/stress testing (e.g., SOASTA, Neotys, Neustar and Keynote) and for developing solutions for simplifying cross-browser testing (e.g., CrossBrowserTesting.com and BrowserStack). However, there is still plenty of work required to improve the overall solutions for cohesive testing heterogeneous environments in the cloud.
- **Mobile:** The Internet-of-Things market will reshape the landscape for testing. We stress that there is a need for either products or technology to form partnerships due to the fact that mobile devices have added a number of new complexities and challenges to the automation of tests.

- **Agile Development:** The growth of agile development practices continues pushing traditional software vendors to enhance their framework to enable smarter, more efficient tests and a strong partnership between developers and testers.
- **Open Source:** The number of open source testing tools will continue to grow (including those from Appvance and Sauce Labs). The Selenium WebDriver in particular will have significant impact on the functional testing of Web applications.

CONCLUSION

We have presented an overview of some of the contemporary system performance testing frameworks. We observed that most of the commercially available system performance testing frameworks have been designed with a strong view of tightly linking business, testing, and development; that integrates the test tool with developers IDEs. Most of the market leaders have broad portfolios covering test management, and functional and performance test automation. All the frameworks are capable to create, manage and execute test automation on the Windows platform, to test Web applications, and with some frameworks focusing on the cloud and mobile applications.

Furthermore, we have demonstrated our general-purpose performance testing framework is simple to implement yet versatile to test the performance of complicated and large-scale enterprise systems.

KEY TERMS AND DEFINITIONS

Bandwidth: The amount of information that can be transmitted in a fixed amount of time over a particular media channel.

CPU Utilization: Determines the percentage of time the processor is busy by measuring the percentage of time the thread of the idle process is running and then subtracting that from 100 percent.

Disk I/O Utilization: The amount of input and output operations on the secondary storage at a certain unit of time.

Latency: The total time spent by a system generated message to travel from its sender (source) to its receiver (destination).

Main Memory Utilization: The amount of RAM used by a particular system at a certain unit of time.

Response Time: The total time taken by a user to wait in invoking a request to a particular system and coming back with a result.

Scalability: A measure of the capability of a system to increase its total output under an increased load when resources (typically hardware) are added.

Speedup: A measure of the relative performance improvement when executing a task. Speedup can be defined by studying the different types of performance metrics such as: throughput and latency.

System Performance Testing: A special type of technical investigation done to determine or

validate the speed, scalability, and/or stability characteristics of the system under test.

Throughput: The capability of a system in handling a certain number of client requests (such as messages or transactions) within a unit of time (such as second or minute).

A Tale of Two Agile Requirements Engineering Practices

S**Pankaj Kamthan***Concordia University, Canada***Terrill Fancott***Concordia University, Canada*

INTRODUCTION

The discipline of software engineering advocates a systematic and disciplined approach towards the development and evolution of software systems. The ecosystem of software engineering is changing constantly, and influences the practice of software engineering. In the past decade, there have been a number of notable strategic changes in industrial software engineering, including the adoption of agile methodologies (Highsmith, 2009). If industrial surveys are any sign, this trend is likely to continue for the foreseeable future.

There are a number of concerns in agile software development, including requirements engineering (Sillitti & Succi, 2005; Zhu, 2009; Leffingwell, 2011). There are different types of agile requirement, of which currently the most common forms are use cases (Jacobson et al., 1992) and user stories (Cohn, 2004). The use cases and user stories have different origins, both in space and in time, but, by being among the practices of scenario-oriented requirements engineering (SORE) (Alexander, 2011), they are not entirely unrelated. The purpose of this article is to situate use cases and user stories in context of each other.

The need for a comparison among concepts arises naturally in many disciplines, and agile requirements engineering is no exception. Indeed, it is suggested by theories of learning, such as constructivism (Piaget, 1952), that upon initial exposure to a new concept C, a comparison between C and other, closely related and relatively

more established, concepts C' is inevitable. This comparison is a necessary prerequisite for creating an understanding of C through assimilation and accommodation, selection, and application. In this article, C is user story and C' is use case.

The rest of the article is organized as follows. First, background and related work are presented. This is followed by introduction of a conceptual framework for systematically comparing use cases and user stories. Next, directions for future research are highlighted. Finally, concluding remarks are given.

BACKGROUND

In this section, a brief background on agile methodologies and requirements engineering is presented, and previous work on comparing use cases and user stories is analyzed.

Agile Methodologies

In the 1990s, a number of limitations of rigidity in approaches for development of certain types of software systems were realized. These limitations made it difficult for organizations that aimed for relatively short release cycles of their products to remain competitive in the market, had relatively small budgets to allocate for their projects, and required richer communication between technical and non-technical stakeholders (including customers and users) to address their needs better.

DOI: 10.4018/978-1-5225-2255-3.ch659

Figure 1. A causal relationship between the success of a software project and the practices of software requirements engineering

The drive to cope with these limitations led to the inception of agility.

The *Agile Manifesto* constitutes the basis for a number of agile methodologies, including Agile Experience Design (AXD), Crystal Clear, Extreme Programming (XP), OpenUP, Scrum, and User-Centered Agile Process (UCAP). The agile methodologies have evolved over time and in certain cases, such as the Discipline Agile Delivery (DAD) process framework (Ambler & Lines, 2012), elements of multiple agile methodologies have been included.

Requirements Engineering

In software engineering, significant emphasis is placed on the requirements engineering, in general, and practices of requirements engineering, in particular, in the light of their impact on the later phases of software development and eventually their influence on the success of the software project (Wiegiers, 2003). This causality is depicted in Figure 1. In requirements engineering, the attention is on the problem so as to devise a desirable and viable solution, namely the software system, which can satisfy the stakeholders.

The agile methodology underlying an agile project determines the type of agile requirement to be adopted. For example, in Crystal Clear and OpenUP, an agile requirement can take the form of a use case (Jacobson et al., 1992) and in AXD, XP, Scrum, and UCAP, an agile requirement can take the form of a user story (Cohn, 2004).

Related Work

The need for understanding the differences between use cases and user stories has been, directly or indirectly, expressed in several places in literature. In the following, previous efforts that compare use cases and user stories are analyzed briefly and chronologically.

The notion of simplicity has been a criterion for comparison between use cases and user stories. In one of the earliest work on user stories (Beck, 2000), it has been pointed out that user stories are “simplified use cases.” However, the meaning of ‘simplification’ and exactly what is “simplified” has not been given.

The structure of the means used for a description has often been a criterion for comparison between use cases and user stories. Indeed, it has

been stated that use cases are “structured” while user stories (in XP) are “unstructured” (Cohn & Paul, 2001), that “use cases are a structured representation of a user story” (Decker et al., 2006), and that “[use cases] are expressed using a constrained (semi-formal) syntax” and that “[user stories] are expressed using natural language prose” (Alexander & Maiden, 2004). However, there are a number of ways of expressing a use case (Cockburn, 2001), and not all of them need to be “structured” or follow a “constrained (semi-formal)” syntax.

The issue of a software requirement treading into software design has been a criterion for comparison between use cases and user stories. For example, it has been asserted that “use cases are more prone to including details of the user interface” (Cohn, 2004) and that “it is usual for use cases to include user interface details” (Monochristou & Vlachopoulou, 2007). However, there are guidelines (Cockburn, 2001; Wiegers, 2003) that explicitly suggest against the inclusion of any user interface specifics in use cases.

It has been concluded, based on a controlled experiment, that use cases can be useful as a complement to user stories (Gallardo-Valencia, Olivera, & Sim, 2007).

Finally, it has been pointed out that there are trade-offs in committing to both use cases and user stories, and that each approaches testing differently (Wiegers & Beatty, 2013).

Table 1. A framework for comparing use Cases and user stories

Discipline	Viewpoint	Criterion
Software Engineering	Project	• Estimate • Schedule
	Process	• Methodology • Development
	People	• Users • Value
	Product	• Scope • Description
	Resource	• Purpose • Maturity

The issues underlying related work can be summarized as follows. The comparison between use cases and user stories is treated as a secondary, not a primary, concern; the comparison is not systematic; and the instrument for comparison has a singular perspective. This article is motivated, in part, by the need to address these issues. To do that, a systematic approach for comparison that rests on the foundations of software engineering is required.

A CONCEPTUAL FRAMEWORK FOR COMPARING USE CASES AND USER STORIES

In this section, use cases and user stories are compared systematically. The purpose of comparison is to facilitate understanding and appropriate use of each.

The comparison is based on a conceptual framework, as given in *Table 1*, consisting of a set of meta-criteria that are decomposed into a set of criteria. The criteria are selected in a manner that they are relevant to software engineering, as well as both to use cases and to user stories. The criteria are considered equally significant.

The conceptual framework is based on the software engineering principle of *separation of concerns* (Ghezzi, Jazayeri, & Mandrioli, 2003). The meta-criteria consist of certain viewpoints considered relevant to software engineering by the *IEEE Software and Systems Engineering Standards Committee*. Figure 2 shows these viewpoints and the interrelationships among them, the dynamics of which can be explained as follows. *People* initiate a *Project* that uses one or more *Resources* to follow a *Process* that produces a *Product* by transforming it (iteratively and incrementally) over space and time. This *Product* could be an intermediate artifact of the software system in question, or the system itself, which evolves from inception to conclusion. For example, a low-fidelity design prototype could be such a *Product*.

Figure 2. The viewpoints and their interrelationships in the conceptual framework

The rest of the section provides details of comparison between use cases and user stories, organized by viewpoints and criteria, highlighting the similarities and differences between them in the process.

Use Cases vs. User Stories: Project-Viewpoint

A comparison of use cases and user stories from a project viewpoint can be based on the following criteria: estimate and schedule.

Criterion: Estimate

Use Cases: In light of their availability early in a software development process, use cases have been recommended as a basis for estimation (Karner, 1993; Mohagheghi, Anda, & Conradi, 2005). The purpose of estimation is to schedule the entire software project. This approach requires the presence of all use cases upfront, and the fact that they all are expressed in a certain manner, for calculating the estimate. However, a use case is not intrinsically related to estima-

tion. Furthermore, software development methodologies that currently support use cases, do not use the estimates based on use cases for planning.

User Stories: A user story must be associated with an estimate. The estimation must be part of a user story development process. In other words, a user story description without an estimate is incomplete. A user story is estimated individually. In both XP and Scrum, the purpose of estimating user stories is short-term planning. In particular, the user story estimate is used for iteration planning and release planning.

Criterion: Schedule

Use Cases: The completion (design and implementation) of a use case is not explicitly time-bound. A single use case could be completed over a number of iterations.

User Stories: The completion of a user story is time-bound. A single user story must be completed in a single iteration. Indeed, if a user story is too large to fit in a single iteration, it must be split into multiple user stories.

Use Cases vs. User Stories: Process-Viewpoint

A comparison of use cases and user stories from a process viewpoint can be based on the following criteria: methodology and development.

Criterion: Methodology

Use Cases: The use cases are originally associated with Objectory. There is explicit support for use cases in Unified Process and its customizations, in ICONIX Process, and in Crystal Clear. In other words, use cases were a part of rigid methodologies initially, and over time became a part of certain agile methodologies. The use case modeling approach itself is iterative, incremental, and interspersed.

User Stories: The user stories are originally associated with XP. There is explicit support for user stories in other agile methodologies such as Scrum, and its extensions such as UCAP and U-SCRUM. The user story creation approach itself is iterative, incremental, and interspersed.

Criterion: Development

Use Cases: The development of a use case model can be based solely on introspection (say, via speculation or self-reference).

User Stories: The development of user stories relies explicitly on extrospection. The social aspect of the development is exhibited in form of proximity (such as, during meetings and interviews), communication, and collaboration, and is considered necessary for elaboration and clarification of user stories. This situation, however, is changing as *crowdsourcing* becomes an accepted means of eliciting users' needs.

Use Cases vs. User Stories: People-Viewpoint

S

A comparison of use cases and user stories from a people viewpoint can be based on the following criteria: users and value.

Criterion: Users

Use Cases: In use case modeling, the users form a subset of human actors. The users elicited during use case modeling can be fictitious or surrogate users (Alexander & Beus-Dukic, 2009). These users may be based on introspection, not necessarily on actual communication with the real users.

User Stories: There must be an actual person behind a (user) role in a given user story. Indeed, a user story is initially expressed for a concrete person, such as a candidate for a *persona*, and is subsequently generalized to a user story for an abstract (user) role.

Criterion: Value

Use Cases: The value provided by a use case to an actor is implicit. This value may or may not be highlighted in a use case description.

User Stories: The value provided by a user story to its (user) role must be explicit. This value serves as a rationale for the user story. The type of value, however, is not specified in the user story definition, and, indeed, may vary across projects and its stakeholders.

Use Cases vs. User Stories: Product-Viewpoint

A comparison of use cases and user stories from a product viewpoint can be based on the following criteria: scope and description.

Criterion: Scope

Use Cases: In general, a use case is larger in scope compared to a user story. An *epic* is a ‘candidate’ user story so large that it can not be completed in a single iteration, and therefore must be split (Cohn, 2004). The scope of a use case is comparable to that of an epic (Collier, 2012).

User Stories: In general, the scope of a user story is comparable to that of a use case ‘normal’ scenario.

Criterion: Description

Use Cases: A use case can be described at multiple levels of details (Cockburn, 2001). The description can be expressed in different modalities, namely text and graphics. A comprehensive textual description of a use case can have several elements, some of which are about the context of use (such as, business rules governing the use case, trigger that initiates the use case, and frequency, pre- and post-conditions of interaction). It is expected that technical terminology is avoided in the description to make it amenable to non-technical stakeholders. However, doing so is unavoidable in a use case model expressed in any of the diagram types of the Unified Modeling Language (UML). The exceptional cases are dealt with in recovery and failure scenarios. The possible types of relationships among use cases are known (Adolph et al., 2003). The description of a use case is not intrinsically related to the existence of test cases. Indeed, the test cases are separated from use cases and, for example, may appear in a test plan, or otherwise in some form of test documentation. A use case description is a relatively permanent artifact that persists throughout the development and maintenance of the software system.

User Stories: A user story has single level of description. The description has a single modality, namely text. A user story description is usually not comprehensive, and contextual information, if any, is minimal and external to the description. It is expected that technical terminology is avoided in the description to make it amenable to non-technical stakeholders. The exceptional cases are dealt with in acceptance tests, not in the user story statement. There is currently no clearly established understanding of the types of relationships among user stories, although this situation is improving (Gomez, Rueda, & Alarcón, 2010). A user story must be associated with acceptance criteria. The acceptance criteria must be part of a user story development process. In other words, a user story description without acceptance criteria is incomplete. The tests are part of the description of a user story. Traditionally, index cards have been used as a medium for disseminating user stories. The tests, by being on the same index card as the user story, are intimately related to that user story. This is in agreement with the ‘T’ of INVEST (Wake, 2002) and INSERT (Patel & Ramachandran, 2009), where ‘T’ expands to Testability, one of the desired quality attributes of a user story. A user story description, at least in the classical sense (Beck, 2000), is intended to be transient: its life is limited to the iteration for which it is formulated. This is in accord with Travel Light, one of the principles of XP. This principle has also been adopted by Agile Modeling (Ambler, 2002). Therefore, user stories need not be archived for long-term use. Indeed, index cards used as a medium for user stories are usually discarded after use (Langr & Ottinger, 2011), although this practice is changing with the increasing use of agile methodologies for geographically dispersed teams, rise of agile project management systems, and needs of maintainability.

Use Cases vs. User Stories: Resource-Viewpoint

A comparison of use cases and user stories from a resource viewpoint can be based on the following criteria: purpose and maturity.

Criterion: Purpose

Use Cases: A use case is a model of the external behavior resulting from the interaction between an actor and the system.
